# The Rényi Capacity and Center

## Barış Nakiboğlu<sup>D</sup>

Abstract—Rényi's information measures—the Rényi information, mean, capacity, radius, and center—are analyzed relying on the elementary properties of the Rényi divergence and the power means. The van Erven–Harremoës conjecture is proved for any positive order and for any set of probability measures on a given measurable space and a generalization of it is established for the constrained variant of the problem. The finiteness of the order  $\alpha$  Rényi capacity is shown to imply the continuity of the Rényi information, both as a family of functions of the order indexed by the priors and as a family of functions of the prior indexed by the orders.

#### I. INTRODUCTION

**I**NFORMATION transmission problems are often posed on models with finite sample spaces or on models with specific noise structures, such as Gaussian or Poisson models. As a result, certain fundamental observations such as the minimax theorem for the Shannon capacity in terms of the Kullback-Leibler divergence or the existence of a unique "capacity achieving output distribution", i.e. the existence of a unique Shannon center, are established either for models with finite sample spaces or for specific noise structures. Kemperman [37] proved these assertions far more generally by interpreting the channel as a set of probability measures on a given measurable space.

In a sense, Kemperman tacitly suggests a purely measure theoretic understanding of the Shannon capacity and center that is separated from their significance in the information transmission problems. Even without the generality afforded by the measure theoretic framework, such an understanding is appealing because Shannon capacity and center come up in various information transmission problems, with very different operational meanings. Consider for example a finite set W of probability mass functions on a finite output set Y.

- If we interpret W as a discrete channel that is to be used multiple times, then the Shannon capacity of W is the largest rate at which one can communicate reliably via the channel W, [62].
- If we interpret W as a collection of sources that is to be encoded by a lossless variable length source code, then the Shannon capacity is a lower bound on the worst redundancy among the members of W, which is off at

most by one for some lossless variable length source code, [16], [21], [58].

In this paper we propose an analogous measure theoretic understanding for the Rényi capacity and center. Our interest in these concepts stems from their operational significance in the channel coding problem; we elucidate that operational significance in our concurrent paper [51]. Because of the generality of the measure theoretic model we adopt in this paper, we can discuss in [51] the operational significance of these concepts for a diverse family of channels in a unified framework. In the current paper our main aim is to present an analysis starting from the measure theoretic first principles and the elementary properties of the Rényi divergence. We will first present a brief overview of the Rényi information, divergence, and mean in §II. Then we define and analyze the Rényi capacity and discuss the implications of its finiteness in §III. We establish the existence of a unique Rényi center through a minimax theorem for the Rényi capacity in terms of the Rényi divergence in §IV. In the rest of §IV we continue the analysis of Rényi capacity and center. We discuss our results and promising directions of inquiry in §V.

Deriving the technical results employed in [51] is one of the main aims of the current paper; however, the scope of our analysis is not restricted to the needs of the particular analysis we present in [51]. We aim to build a more complete understanding of Rényi's information measures that might lead us to new analysis techniques for the problems we investigate in [51] or for other information transmission problems involving Rényi's information measures. Our abstract and general framework is conducive to this purpose; in addition it allows us to observe certain phenomena that cannot be observed in simpler models. For example, the Rényi capacity is either a continuous function of the order on  $(0, \infty)$  or a finite and continuous function of the order on  $(0, \phi]$  that is infinite on  $(\phi, \infty)$  for some  $\phi \in [1, \infty)$ . This dichotomy, however, cannot be observed with models with finite W or finite Y because the Rényi capacity is bounded if either W or Y is finite. See Lemma 15 and the following discussion for more details.

Rényi [56] provided an axiomatic characterization of a family of divergences for pairs of probability mass functions on a given finite sample space; the resulting family of divergences, parametrized by positive real numbers, are named after him. The definition of the Rényi divergence has been extended to pairs of probability measures. Recently, van Erven and Harremoës provided a comprehensive investigation of various properties of the Rényi divergence in [18]. For any  $\alpha$  in  $[0, \infty]$ , the order  $\alpha$  Rényi divergence between probability measures wand q, denoted by  $D_{\alpha}(w \parallel q)$ , is zero when w is equal to qand non-negative when w is not equal to q. Hence, given a measurable space  $(\mathcal{Y}, \mathcal{Y})$  we can use the order  $\alpha$  Rényi divergence to measure the spread of any set of probability

measures W relative to any probability measure q on  $(\mathcal{Y}, \mathcal{Y})$  as follows:

$$S_{\alpha,\mathcal{W}}(q) \triangleq \sup_{w \in \mathcal{W}} D_{\alpha}(w \| q).$$
(1)

 $S_{\alpha,\mathcal{W}}(q)$  is called *the order*  $\alpha$  *Rényi radius of*  $\mathcal{W}$  *relative to* q. By taking the infimum of  $S_{\alpha,\mathcal{W}}(q)$  over all probability measures q on  $(\mathcal{Y}, \mathcal{Y})$ , we get an absolute measure of the spread of  $\mathcal{W}$ , called *the order*  $\alpha$  *Rényi radius of*  $\mathcal{W}$ ,

$$S_{\alpha,\mathcal{W}} \triangleq \inf_{q \in \mathcal{P}(\mathcal{Y})} \sup_{w \in \mathcal{W}} D_{\alpha}(w \| q).$$
(2)

Any probability measure q on the measurable space  $(\mathcal{Y}, \mathcal{Y})$  satisfying  $S_{\alpha, \mathcal{W}}(q) = S_{\alpha, \mathcal{W}}$ , is called *an order*  $\alpha$  *Rényi center* of  $\mathcal{W}$ . The order one Rényi divergence is the Kullback-Leibler divergence; hence the order one Rényi radius and center are the Shannon radius and center referred to in [37].

The Shannon capacity, defined as the supremum of the mutual information, is another measure of the spread of a set of probability measures on a given measurable space. In order to have a parametric generalization of the Shannon capacity, similar to the one provided by the Rényi radius to the Shannon radius, we need a parametric generalization of the mutual information. Sibson [68] proposed one such parametric generalization using the Rényi divergence, called the Rényi information, see Definition 4. For any set of probability measures W on a given measurable space  $(\mathcal{Y}, \mathcal{Y})$ , probability mass function p on W, and positive real number  $\alpha$ ,  $I_{\alpha}(p; W)$  is *the order*  $\alpha$  *Rényi information*<sup>1</sup> *for prior* p. The order one Rényi information equals to the mutual information. For other positive real orders, the order  $\alpha$  Rényi information can be described in terms of Gallager's function introduced in [20]:

$$I_{\alpha}(p; \mathcal{W}) = \left. \frac{E_0(\rho, p)}{\rho} \right|_{\rho = \frac{1-\alpha}{\alpha}} \quad \forall \alpha \in \Re_+ \setminus \{1\}$$
(3)

where Gallager's function  $E_0(\rho, p)$  is defined for  $\rho > -1$  as

$$E_0(\rho, p) \triangleq -\ln \int \left( \sum_{w} p(w) (\frac{\mathrm{d}w}{\mathrm{d}v})^{\frac{1}{1+\rho}} \right)^{1+\rho} \nu(\mathrm{d}y). \quad (4)$$

The order  $\alpha$  Rényi capacity  $C_{\alpha,W}$  is defined as the supremum of the order  $\alpha$  Rényi information  $I_{\alpha}(p;W)$  over all priors p.

There are at least two other ways to define the Rényi information for which the order one Rényi information is equal to the mutual information: one by Arimoto [3] and another one by Augustin [5] and Csiszár [13]. A review of these three definitions of the Rényi information has recently been provided by Verdú [74]. Assuming W and  $\mathcal{Y}$  to be finite sets, Csiszár showed that the order  $\alpha$  Rényi capacity for all three definitions of the Rényi information are equal to one another and to the order  $\alpha$  Rényi radius, [13, Proposition 1].

The extension of Kemperman's result [37, Th. 1] about the Shannon capacity and center given in Theorem 1, presented in the following, is among the most important observations about the Rényi capacity and center. Theorem 1 establishes the equality of  $C_{\alpha,W}$  and  $S_{\alpha,W}$  for any positive order  $\alpha$  and set of probability measures W. Furthermore, it asserts the existence of a unique order  $\alpha$  Rényi center  $q_{\alpha,W}$  whenever  $C_{\alpha,W}$  is finite

and characterizes the unique order  $\alpha$  Rényi center in terms of the order  $\alpha$  Rényi means. These observations, however, have been reported in various forms before, at least partially. Augustin [4] considered the orders in (0, 1), proved a result equivalent to Theorem 1 for finite W's and described how this result can be extended to arbitrary W's. Later, Augustin proved [5, Thm. 26.6'], implying Theorem 1 for all orders in (0, 2). Csiszár [13, Proposition 1] proved the equality  $C_{\alpha,W} = S_{\alpha,W}$ for arbitrary positive order  $\alpha$  assuming W and Y are finite sets.

The equality of capacity to radius and the existence of a unique center, are phenomena that have been observed repeatedly in various contexts. In order to clarify the standing of Theorem 1 among these results, we provide a more comprehensive discussion of the previous work on these fundamental observations in §I-A.

The current paper and the concurrent paper [51] grew out of a desire to understand Augustin's proofs of the sphere packing bound given in [4] and [5] more intuitively. Augustin's proofs are important because, among other things, they are the only proofs of the sphere packing bound for non-stationary product channels, even for the case of discrete channels. Concepts of Rényi capacity, radius, and center provide a way to express the principal novelty of Augustin's method in a succinct and intuitive way. We discuss the novel observation underlying Augustin's method and its promise briefly in §I-B.

Similar to Theorem 1, some of the observations that we discuss in the paper have been reported before either in terms of Rényi's information measures [13], [68] or in terms of other related quantities, such as Gallager's function, [4], [5], [20], [22]. But we also have a number of new observations that have not been reported before. We provide a tally of our most important contributions in §I-C.

We conclude the current section with a summary of our notational conventions presented in §I-D. It is worth mentioning that only §I-D is necessary to understand the rest of the paper; readers may bypass other parts of the current section depending on their interest and background.

#### A. Radius, Center, and Capacity

The concepts of radius and center, as we use them, are analogous to their counter parts in Euclidean geometry. Let W be a set of points in the *n* dimensional Euclidean space  $\Re^n$  and *q* be a point in the same space. Then one measure of the spread of W relative to *q* is the infimum of the radii of the *q*-centered spheres including all points of W, called *the Chebyshev radius of* W *relative to q*:

$$\mathcal{S}_{\mathcal{W}}(q) \triangleq \sup_{w \in \mathcal{W}} \|w - q\|_2 \quad \forall \mathcal{W} \subset \mathfrak{R}^n, q \in \mathfrak{R}^n$$

If we do not require the centers of the spheres to be at a given point q, then we get an absolute measure of the spread of W, called *the Chebyshev radius of* W:

$$\mathcal{S}_{\mathcal{W}} \triangleq \inf_{q \in \mathfrak{R}^n} \sup_{w \in \mathcal{W}} \|w - q\|_2 \quad \forall \mathcal{W} \subset \mathfrak{R}^n$$

If  $S_W$  is finite, then there exists a unique Chebyshev center  $q_W$  satisfying  $S_W(q_W) = S_W$ .

For any set of points in a metric space  $(\mathcal{X}, d)$ , one can define the Chebyshev radius by replacing  $\Re^n$  with  $\mathcal{X}$ 

<sup>&</sup>lt;sup>1</sup>Sibson defines "the information radius of order  $\alpha$ " through an infimum and then derives a closed form expression for it in [68, Th. 2.2]. We take that closed form expression as the definition of the order  $\alpha$  Rényi information.

and  $||w - q||_2$  with d(w, q) in the definition. However, neither the existence nor the uniqueness of the Chebyshev center is a foregone conclusion for such generalizations. Garkavi [23, Th. 1] provides a three point set in a Banach space that does not have a Chebyshev center. In the Hamming space of length two binary strings, both (0,0) and (1,1)are Chebyshev centers of the set  $W = \{(0,1), (1,0)\}$ . See [2, Ch. 15], for a discussion of these concepts on the inner product spaces.

The Chebyshev radius is, in a sense, special because it is defined via the distance measure —the metric corresponding to the norm of the space for normed spaces and the metric of the space for metric spaces— that is a part of the description of the space. In principle, one can measure the relative and the absolute spread of the subsets of  $\mathcal{X}$  using any non-negative function g on  $\mathcal{X} \times \mathcal{X}$  satisfying g(x, x) = 0 for all  $x \in \mathcal{X}$  and define a center accordingly. However, neither the existence nor the uniqueness of such a center is guaranteed.

When  $\mathfrak{X}$  in the above formulation is the space of all probability measures  $\mathcal{P}(\mathcal{Y})$  on a measurable space  $(\mathcal{Y}, \mathcal{Y})$ , one can measure the spread of a subset  $\mathcal{W}$  of  $\mathcal{P}(\mathcal{Y})$  using the Kullback-Leibler divergence. The resulting radius is nothing but the Shannon radius of W and whenever the Shannon radius is finite the existence of a unique Shannon center follows from Kemperman's result [37, Th. 1]. The other assertion of Kemperman's result [37, Th. 1] is the equality of the Shannon radius of W and the Shannon capacity of W, defined as the supremum of the mutual information I(p; W) over all probability mass functions p on W. For the case where both Wand Y are finite sets, Kemperman's result was already known at the time [22, Th. 4.5.1]; Kemperman [37] attributes this special case to Shannon [64]. For the case when Y is a finite set, first Gallager [21, Th. A] and then Davisson and Leon-Garcia [16, Th. 3] proved results equivalent to Kemperman's. Later, Haussler [32] proved Kemperman's result assuming y to be a complete separable metric space, i.e. Polish space, and  $\mathcal{Y}$  to be the associated Borel  $\sigma$ -algebra.

Theorem 1, which we prove in the following, extends Kemperman's result to the Rényi capacity and center of other orders. The existence of a unique center under the finite capacity hypothesis and the equality of the capacity and the radius have been confirmed in other contexts, as well.

1) Radius for *f*-Divergence: Csiszár [7]. [9], Morimoto [43], and Ali and Silvey [1] defined the f-divergence using convex functions, satisfying f(1) = 0. The divergence<sup>2</sup> Kullback-Leibler is the *f*-divergence corresponding to the function  $f(x) = x \ln x$  defined for x > 0 with f(0) = 0 (i.e., a continuous extension of f at zero). For any convex function f satisfying f(1) = 0, the absolute and relative *f*-radius are defined in terms of the corresponding *f*-divergence as follows:

$$\begin{aligned} \mathcal{S}_{f,\mathcal{W}}(q) &\triangleq \sup_{w \in \mathcal{W}} \mathcal{D}_{f}(w \| q) , \\ \mathcal{S}_{f,\mathcal{W}} &\triangleq \inf_{q \in \mathcal{P}(\mathcal{Y})} \sup_{w \in \mathcal{W}} \mathcal{D}_{f}(w \| q) . \end{aligned}$$

The f-information and the f-capacity are defined in terms of corresponding f-divergence as follows

$$\begin{aligned} \mathcal{I}_f(p; \mathcal{W}) &\triangleq \inf_{q \in \mathcal{P}(\mathcal{Y})} \mathcal{D}_f(p \circledast \mathcal{W} \| p \otimes q) , \\ \mathcal{C}_{f, \mathcal{W}} &\triangleq \sup_{p \in \mathcal{P}(\mathcal{W})} \mathcal{I}_f(p; \mathcal{W}) \end{aligned}$$

where  $p \circledast W$  is the probability measure whose marginal distribution on the support of p is p and whose conditional distribution is w and  $p \otimes q$  is the product measure.

The mutual information<sup>3</sup> is the *f*-information corresponding to  $f(x) = x \ln x$ . For W's that are finite, Csiszár [11, Th. 3.2] proved the following two assertions:

- $C_{f,W} = S_{f,W}$  for any f that is strictly convex at 1.
- There exists a unique *f*-center for any *f* that is strictly convex, provided that  $S_{f,W}$  is finite.

For *f*'s that are strictly convex, it seems both assertions of Csiszár [11, Th. 3.2] can be extended to arbitrary W's using the technique employed by Kemperman, as Kemperman himself suggested in [37]. Gushchin and Zhdanov [28] proved that  $C_{f,W}$  equals to  $S_{f,W}$  for any convex function *f* and any set of probability measures W provided that  $\mathcal{Y}$  is a complete separable metric space, i.e. Polish space, and  $\mathcal{Y}$  is the associated Borel  $\sigma$ -algebra.

2) Radius in Quantum Information Theory: In this paper, we assume W to be a set of probability measures on a given measurable space. This is a generalization of the case when  $\mathcal{W}$  is a set of probability mass functions on a given finite set  $\mathcal{Y}$ , i.e. the finite sample space case. Another generalization of the finite sample space case is obtained by assuming W to be a set of  $|\mathcal{Y}|$ -by- $|\mathcal{Y}|$  positive semidefinite, trace one, Hermitian matrices. In quantum information theory such matrices are called the density matrices; they represent the states of a  $|\mathcal{Y}|$  dimensional Hilbert space  $\mathcal{H}$ , [34, §1.2]. The set of all such states is denoted by  $\mathcal{S}(\mathcal{H})$ . There is a one-to-one correspondence between the diagonal members of  $\mathcal{S}(\mathcal{H})$  and the probability mass functions on *Y*. As a result, statements about subsets of  $\mathcal{S}(\mathcal{H})$  can be interpreted as generalizations of the corresponding statements about sets of probability mass functions on *Y*.

The definition of the Kullback-Leibler divergence has been extended to the members of S(H); it is, however, customarily called *the quantum relative entropy* [34, §3.1.1]:

$$D(w \parallel q) \triangleq \operatorname{Tr} w(\ln w - \ln q) \quad \forall w, q \in \mathcal{S}(\mathcal{H}).$$
(5)

This definition can be interpreted as an extension because for the diagonal members of  $S(\mathcal{H})$ , the quantum relative entropy as defined in (5) is equal to the Kullback-Leibler divergence between the corresponding probability mass functions. For any subset W of  $S(\mathcal{H})$ , the quantum Shannon radius is defined as  $\inf_{q \in S(\mathcal{H})} \sup_{w \in W} D(w || q)$ .

The definition of mutual information has been extended as well, but it is called *the transmission information* [34, §4.1.1]:

$$I(p; \mathcal{W}) \triangleq \sum_{w \in \mathcal{W}} p(w) D(w \| q_p) \quad \forall p \in \mathcal{P}(\mathcal{W})$$
(6)

<sup>3</sup>For positive finite orders other than one the Rényi information can be written in terms of an *f*-information, using the analogous relation for divergences:  $I_{\alpha}(p; \mathcal{W}) = \frac{1}{\alpha-1} \ln(1 + (\alpha - 1)\mathcal{I}_{f}(p; \mathcal{W}))$  for  $f(x) = \frac{x^{\alpha} - 1}{\alpha-1}$ .

<sup>&</sup>lt;sup>2</sup>For positive finite orders other than one the Rényi divergence is not an *f*-divergence itself; but it can be written in terms of an *f*-divergence:  $D_{\alpha}(w||q) = \frac{1}{\alpha-1} \ln(1+(\alpha-1)\mathcal{D}_f(w||q))$  for  $f(x) = \frac{x^{\alpha}-1}{\alpha-1}$ , as previously pointed out in [8, eq. (14)], [9, eq. (1.10)], [10, eq. (6)], [59, eq. (1)], and [60, eq. (80)].

where  $q_p = \sum_{w \in W} p(w)w$ . Note that when W includes only diagonal members of S(H), the above quantity equals to the mutual information for the prior p on the corresponding set of probability mass functions. The quantum Shannon capacity is defined as the supremum of I(p;W) over all probability mass functions p on W with finite support.

The quantum Shannon capacity and radius are equal to one another for arbitrary  $\mathcal{W} \subset \mathcal{S}(\mathcal{H})$  provided that  $\mathcal{H}$  is a finite dimensional Hilbert space, [34, Th. 4.1], [53, Th. 3.5], [61, eq. (19)]. This implies the equality of Shannon capacity and radius in the classical case provided that  $\mathcal{Y}$  is a finite set. However, neither Kemperman's result in [37] nor the weaker result by Haussler in [32] require  $\mathcal{Y}$  to be finite. Thus those results are not subsumed by the quantum Information theoretic versions of Kemperman's result presented in [34], [53], and [61].

The situation is similar for the quantum Rényi capacity, radius, and center. All the results on the equality of the quantum Rényi capacity and radius that we are aware of [15, Th. 6], [34, eq. (4.74)], [39, Lemma I.3], [44, Th. IV.8], [45, Proposition 4.2], and [75, Lemma 14] assume W to be a subset of  $S(\mathcal{H})$  for a finite dimensional Hilbert space  $\mathcal{H}$ . Hence, to the best of our knowledge, Theorem 1 is not subsumed by any of the known results in quantum information theory.

#### B. Augustin's Method and the Rényi Center

Augustin's proof of the sphere packing bound in [4] is one of the first few complete proofs of the sphere packing bound. Unlike its contemporaries by Shannon et al. [63] and by Haroutunian in [29], Augustin's proof does not assume either the stationarity of the channel or the finiteness of the input set because it does not rely on a type based expurgation (i.e. a fixed composition argument). After decades, Augustin's proofs in [4] and [5] are still the only proofs of the sphere packing bound for non-stationary product channels, even in the finite input alphabet case. Augustin's method has been applied to problems with feedback, as well. Using a variant of his method, Augustin [5] provides a proof sketch for the derivation of the sphere packing bound for codes on discrete stationary product channels with feedback; a complete proof following this proof sketch can be found in [49]. What we call the discrete stationary product channels with feedback are customarily called DMCs with feedback.

Despite their strength and generality, Augustin's derivations of the sphere packing bound is scarcely known to date, even among the specialists working on related problems. In [51, §IV], we derive sphere packing bounds using Augustin's method in a way that makes the roles of the Rényi capacity and center more salient and precise. Our bound for the product channels is sharper than the corresponding bounds in [4] and [5]. In [51, §V], we present a new proof of the sphere packing bound for the discrete product channels with feedback that facilitates the ideas of Haroutunian [30] and Sheverdyaev [66], as well as Augustin [4], [5]. Our new proof for the case with feedback holds for non-stationary channels satisfying certain stationarity hypothesis. In [51, Appendix B], we discuss other aspects of the operational significance of Rényi capacity and information for the channel coding problem.

The generality and strength of Augustin's results compel one to ask: What is the principle behind Augustin's proofs of the sphere packing bound? A succinct answer exists for those who are already familiar with the concepts of Rényi capacity, radius and center.<sup>4</sup> In our judgment, the novel observation behind Augustin's proofs is the following:

$$\lim_{\phi \to a} S_{\alpha, \mathcal{W}}(q_{\phi, \mathcal{W}}) = C_{\alpha, \mathcal{W}}.$$

This observation seems benign enough to hold for other parametric families of divergences and corresponding capacities, radii, and centers. Thus we believe that Augustin's method can probably be used to derive tight outer bounds in other information transmission problems, as well.

## C. Main Contributions

- (1) If  $\mathcal{W}$  and  $\mathcal{Y}$  are finite sets, the continuity of the Rényi information is evident, both as a function of the order and as a function of the prior. In their proof of the sphere packing bound [63, p. 101], while proving the continuity of the Rényi capacity in the order on (0, 1) for the finite W and Y case— Shannon, Gallager, and Berlekamp asserted that the Rényi information is in fact equicontinuous as a family of functions of the order on (0, 1) indexed by the priors. We strengthen their assertion by replacing the finiteness hypothesis on the sets Wand  $\mathcal{Y}$  with a finiteness hypothesis for the Rényi capacity, including orders greater than one, and establishing uniformity of the equicontinuity, see Lemma 16-(f). Furthermore, we show that the Rényi information is, also, uniformly equicontinuous when considered as a family of functions of the prior indexed by the orders, see Lemma 16-(e).
- (2) Reflecting on [18, Th. 37] for countable Y's at a = ∞, van Erven and Harremoës conjectured the following: Conjecture [18, Conjecture 1]: If S<sub>a,W</sub> < ∞ for an a in (0, ∞] and a W ⊂ P(Y) then there exists a unique q<sub>a,W</sub> ∈ P(Y) satisfying S<sub>a,W</sub> = sup<sub>w∈W</sub>D<sub>a</sub>(w|| q<sub>a,W</sub>). Furthermore, for all q ∈ P(Y) we have

$$\sup_{w \in \mathcal{W}} D_{\alpha}(w \| q) \ge S_{\alpha, \mathcal{W}} + D_{\alpha}(q_{\alpha, \mathcal{W}} \| q).$$

This conjecture is confirmed in Lemma 19 for the first time.<sup>5</sup> Lemma 19 implicitly asserts the existence of a unique  $q_{\alpha,W}$ , which is proved in Theorem 1. This assertion, however, is not entirely new; Augustin proved an equivalent assertion for orders in (0, 2) in [5, Th. 26.6'] and gave a proof sketch for an equivalent assertion for orders in (0, 1) in [4].

In Appendix A, we define  $C_{\alpha,W,\mathcal{A}}$  as the supremum of  $I_{\alpha}(p;W)$  over all priors p in  $\mathcal{A}$  and generalize the

<sup>&</sup>lt;sup>4</sup>Although Augustin does not work with them either in [4] or in [5], one can restate his observations in terms of Rényi's information measures.

 $<sup>^{5}</sup>$ We were notified in [31] that van Erven and Harremoës had a proof establishing their conjecture in [18] under some regularity conditions, at the time.

van Erven-Harremoës bound to the convex A case, see Definition 8 and Lemma 25.

- (3) Our framework allows us to pose and answer certain questions that are non-trivial only for infinite W's, i.e. infinite subsets of P(Y).
  - (a) There exists a countable subset W' of W such that  $C_{\alpha,W'} = C_{\alpha,W}$  for all  $\alpha$  in  $[0, \infty]$ , Lemma 15-(b).
  - (b) If C<sub>η,W</sub> is finite, then for all ε > 0 there exists a finite subset W' of W such that C<sub>α,W</sub> > C<sub>α,W</sub> − ε for all α in [ε, η], Lemma 15-(g).
  - (c) C<sub>α,C1W</sub> = C<sub>α,W</sub> for all α in (0,∞] where c1W is the closure of W in the topology of setwise convergence, Lemma 24-(b). This has been pointed out by Csiszár and Körner for α equals one case for finite Y in [14, Problem 8.10(b)].

#### D. Notational Conventions

For any set  $\mathcal{Y}$ , we denote the set of all subsets of  $\mathcal{Y}$  by  $2^{\mathcal{Y}}$ and the set of all probability measures on finite subsets of  $\mathcal{Y}$ by  $\mathcal{P}(\mathcal{Y})$ . For each  $p \in \mathcal{P}(\mathcal{Y})$ , i.e. for each probability mass function (p.m.f.), we denote the set of all y's in  $\mathcal{Y}$  for which p(y) > 0, by  $\operatorname{supp}(p)$  and call it the support of p.

We call the pair  $(\mathcal{Y}, \mathcal{Y})$  a measurable space iff  $\mathcal{Y}$  is a  $\sigma$ -algebra of the subsets of  $\mathcal{Y}$ . On a measurable space  $(\mathcal{Y}, \mathcal{Y})$ , we denote the set of all finite signed measures by  $\mathcal{M}(\mathcal{Y})$ , the set of all finite measures by  $\mathcal{M}_0^+(\mathcal{Y})$ , the set of all non-zero finite measures by  $\mathcal{M}^+(\mathcal{Y})$ , and the set of all probability measures by  $\mathcal{P}(\mathcal{Y})$ .

A measure  $\mu$  on the measurable space  $(\mathcal{Y}, \mathcal{Y})$  is absolutely continuous with respect to another measure  $\nu$  on  $(\mathcal{Y}, \mathcal{Y})$ , i.e.  $\mu \prec \nu$ , iff  $\mu(\mathcal{E}) = 0$  for any  $\mathcal{E} \in \mathcal{Y}$  such that  $\nu(\mathcal{E}) = 0$ . Measures  $\mu$  and  $\nu$  are equivalent, i.e.  $\mu \sim \nu$ , iff  $\mu \prec \nu$  and  $\nu \prec \mu$ . Measures  $\mu$  and  $\nu$  are singular, i.e.  $\mu \perp \nu$ , iff there exists an  $\mathcal{E} \in \mathcal{Y}$  such that  $\mu(\mathcal{E}) = \nu(\mathcal{Y} \setminus \mathcal{E}) = 0$ .

A subset W of  $\mathcal{M}^{+}(\mathcal{Y})$  is absolutely continuous with respect to a measure v, i.e.  $W \prec v$ , iff  $w \prec v$  for all  $w \in W$ . A  $\sigma$ -finite measure v is a reference measure for W iff  $W \prec v$ . A subset W of  $\mathcal{M}^{+}(\mathcal{Y})$  is uniformly absolutely continuous with respect to v, i.e.  $W \prec^{uni} v$ , iff for every  $\epsilon > 0$  there exists a  $\delta > 0$ such that  $w(\mathcal{E}) < \epsilon$  for all  $w \in W$  provided that  $v(\mathcal{E}) < \delta$ . By [67, p. 366, Th. 2],  $\mu \prec v$  iff  $\{\mu\} \prec^{uni} v$ . Two subsets Wand  $\mathcal{U}$  of  $\mathcal{P}(\mathcal{Y})$  are singular, i.e.  $W \perp \mathcal{U}$ , iff there exists an  $\mathcal{E} \in \mathcal{Y}$  such that  $w(\mathcal{E}) = 0$  for all  $w \in W$  and  $u(\mathcal{Y} \setminus \mathcal{E}) = 0$  for all  $u \in \mathcal{U}$ .

We denote the Borel  $\sigma$ -algebra for the usual topology of the real numbers by  $\mathcal{B}(\mathfrak{R})$ . We denote the essential supremum of a  $\mathcal{Y}$ -measurable, i.e.  $(\mathcal{Y}, \mathcal{B}(\mathfrak{R}))$ -measurable, function f for the measure  $\nu$  on  $(\mathcal{Y}, \mathcal{Y})$  by ess sup, f(y), i.e.

ess sup<sub>v</sub> 
$$f \triangleq \inf\{\gamma : \nu(\{y : f(y) > \gamma\}) = 0\}$$
.

We denote the integral of a measurable function f on  $(\mathcal{Y}, \mathcal{Y})$ with respect to the measure  $\nu$  by  $\int f\nu(dy)$  or  $\int f(y)\nu(dy)$ . We denote the integral by  $\int f dy$  or  $\int f(y) dy$ , as well, if it is on the real line and with respect to the Lebesgue measure. If  $\nu$  is a probability measure, then we also call the integral of f with respect to  $\nu$  the expectation of f or the expected value of f and denote it by  $\mathbf{E}_{\nu}[f]$  or  $\mathbf{E}_{\nu}[f(\mathbf{Y})]$ . While discussing the continuity of measure valued functions and functions defined on sets of measures, we use either the topology of setwise convergence or the total variation topology. The topology of setwise convergence is the topology generated by the sets of the form  $\{\mu : |\mu(\mathcal{E}) - t| < \epsilon\}$  for some  $\mathcal{E} \in \mathcal{Y}, t \in \Re_+, \epsilon \in \Re_+$ ; see [6, §4.7(v)] for a more detailed discussion. The total variation topology is the metric topology generated by the total variation norm. For any  $\mu$  in  $\mathcal{M}(\mathcal{Y})$  the total variation norm of  $\mu$  is defined as

$$\|\mu\| \triangleq \sup_{\mathcal{E} \in \mathcal{Y}} \mu(\mathcal{E}) - \mu(\mathcal{Y} \setminus \mathcal{E}).$$

As a consequence of the Lebesgue decomposition theorem [17, Th. 5.5.3] and the Radon-Nikodym theorem [17, Th. 5.5.4] we have

$$\|\mu\| = \int \left|\frac{\mathrm{d}\mu}{\mathrm{d}\nu}\right| \nu(\mathrm{d}y) \quad \forall \mu, \nu : \mu \prec \nu.$$

Our notation will be overloaded for certain symbols; however, the relations represented by these symbols will be clear from the context. We denote the products of topologies [17, p. 38],  $\sigma$ -algebras [17, p. 118], and measures [17, Th. 4.4.4] by  $\otimes$ . We denote the Cartesian product of sets [17, p. 38] by  $\times$ . We denote the absolute value of real numbers and the size of sets by  $|\cdot|$ . For extended real valued functions f and g on  $\mathcal{Y}$ ,  $f \leq g$  iff  $f(y) \leq g(y)$  for all  $y \in \mathcal{Y}$ . For measures  $\mu$  and  $\nu$  on  $(\mathcal{Y}, \mathcal{Y})$ ,  $\mu \leq \nu$  iff  $\mu(\mathcal{E}) \leq \nu(\mathcal{E})$  for all  $\mathcal{E} \in \mathcal{Y}$ .

For  $x, y \in \mathfrak{N}$ ,  $x \wedge y$  is the minimum of x and y. For extended real valued functions f and g on  $\mathcal{Y}$ ,  $f \wedge g$  is the pointwise minimum of f and g. For  $\mu, w \in \mathcal{M}(\mathcal{Y})$ ,  $\mu \wedge w$  is the unique measure satisfying  $\frac{d\mu \wedge w}{d\nu} = \frac{d\mu}{d\nu} \wedge \frac{dw}{d\nu}$  for any  $\nu$  satisfying  $\mu \prec \nu$ and  $w \prec \nu$ . If  $\mathcal{F}$  is a set of real valued functions, then  $\wedge_{f \in \mathcal{F}} f$ is the extended real valued function obtained by taking the pointwise infimum of f's in  $\mathcal{F}$ . For a  $\mathcal{U} \subset \mathcal{M}(\mathcal{Y})$  satisfying  $w \leq u$  for all  $u \in \mathcal{U}$  for some  $w \in \mathcal{M}(\mathcal{Y})$ ,  $\wedge_{u \in \mathcal{U}} u$  is the measure which is the infimum of  $\mathcal{U}$  with respect to the partial order  $\leq$ . The existence of a unique infimum is guaranteed by [6, Th. 4.7.5]. We use the symbol  $\vee$  analogously to  $\wedge$  but we represent maxima and suprema with it, rather than minima and infima.

## II. PRELIMINARIES

We commence our discussion by defining the mean measure and analyzing it, first as a function of the order for a given prior then as a function of the prior for a given order. After that we define the Rényi information using the mean measure and analyze it as a function of the order and the prior using the analysis of the mean measure. Then we define the Rényi divergence and review those features of it that will be needed in our analysis. We conclude the current section by defining the Rényi mean and deriving an alternative expression for the Rényi information in terms of the Rényi divergence using the Rényi mean.

## A. The Mean Measure

The weighted power means are generalizations of the weighted arithmetic mean. For any positive real number  $\alpha$  and p.m.f. *p* on non-negative real numbers, the order  $\alpha$  mean

for the prior *p* is  $(\sum_{x} p(x)x^{\alpha})^{1/\alpha}$ . For any prior *p*, the order  $\alpha$  weighted mean is a nondecreasing and continuously differentiable function of  $\alpha$  on  $\Re_+$ . Hence we can calculate its limit as  $\alpha$  approaches zero, or infinity, using the L'Hospital's rule [57, Th. 5.13]:

$$\lim_{\alpha \downarrow 0} \left( \sum_{x} p(x) x^{\alpha} \right)^{1/\alpha} = \prod_{x} x^{p(x)}$$
$$\lim_{\alpha \uparrow \infty} \left( \sum_{x} p(x) x^{\alpha} \right)^{1/\alpha} = \max_{x: p(x) > 0} x.$$

The order  $\alpha$  mean of measures for the prior p is defined via the pointwise order  $\alpha$  mean of their Radon-Nikodym derivatives for the prior p. In the following, we confine our discussion to the means of probability measure.

Definition 1: Let p be a p.m.f. on  $\mathcal{P}(\mathcal{Y})$  and v be a reference measure for w's with positive p(w). Then the order  $\alpha$  mean of the Radon-Nikodym derivatives for the prior p is

$$\frac{\mathrm{d}\mu_{\alpha,p}}{\mathrm{d}\nu} \triangleq \begin{cases} \prod_{w:p(w)>0} \left(\frac{\mathrm{d}w}{\mathrm{d}\nu}\right)^{p(w)} & \text{if } \alpha = 0\\ \left(\sum_{w} p(w) \left(\frac{\mathrm{d}w}{\mathrm{d}\nu}\right)^{\alpha}\right)^{\frac{1}{\alpha}} & \text{if } \alpha \in \Re_{+} \quad \nu\text{-a.e.} \quad (7)\\ \max_{w:p(w)>0} \frac{\mathrm{d}w}{\mathrm{d}\nu} & \text{if } \alpha = \infty \end{cases}$$

The order  $\alpha$  mean measure for the prior p is defined as

$$\mu_{\alpha,p}(\mathcal{E}) \triangleq \int_{\mathcal{E}} \frac{\mathrm{d}\mu_{\alpha,p}}{\mathrm{d}\nu} \nu(\mathrm{d}y) \qquad \forall \mathcal{E} \in \mathcal{Y}.$$
(8)

In (7) and throughout this section sums of the form  $\sum_{w}$  stands for sums of the form  $\sum_{w:p(w)>0}$ . In (7), *w* is a dummy variable used to express the elements of  $\mathcal{P}(\mathcal{Y})$ , i.e. probability measures on  $(\mathcal{Y}, \mathcal{Y})$ . The probability mass assigned to each *w* by *p* is denoted by p(w). The reference measure *v* is absent from the symbol for the mean measure because mean measure does not depend on the choice of the reference measure: Let  $\tilde{\mu}_{\alpha,p}$  be the mean measure obtained using a reference measure  $\tilde{\nu}$  instead of *v*; then

$$\mu_{\alpha,p}(\mathcal{E}) = \widetilde{\mu}_{\alpha,p}(\mathcal{E}) \qquad \forall \alpha \in [0,\infty] \text{ and } \forall \mathcal{E} \in \mathcal{Y}.$$

This follows from a standard application of the Lebesgue decomposition theorem [17, Th. 5.5.3] and the Radon-Nikodym theorem [17, Th. 5.5.4].

We are interested in the mean measure primarily as a tool to define and analyze the Rényi information. Augustin [5, §26] introduced the mean measure and derived some of the observations we present in Lemmas 1-4, albeit for different parameterizations of the order. Augustin, however, did not define or analyze the Rényi information in [5]. Proofs of Lemmas 1-4 can be found in [48, Appendix D].

Lemma 1: Let p be a p.m.f. on  $\mathcal{P}(\mathcal{Y})$ .

- (a)  $\mu_{\alpha,p} \sim \mu_{1,p}$  and  $|\operatorname{supp}(p)|^{-\frac{1}{\alpha}} \leq \|\mu_{\alpha,p}\| \leq |\operatorname{supp}(p)|$ for any  $\alpha \in (0, \infty]$ . Furthermore,  $\|\mu_{1,p}\| = 1$ .
- (b)  $\mu_{0,p} \prec w$  for any  $w \in \operatorname{supp}(p)$  and  $\|\mu_{0,p}\| \leq 1$ .

The main consequence of Lemma 1 is that  $\mu_{\alpha,p} \prec \mu_{1,p}$  for all  $\alpha \in [0, \infty]$ . Hence, we can describe and analyze the mean measures via their Radon-Nikodym derivatives with respect to the order one mean measure. We build our analysis of the mean measure as a function of the order around this observation. First, we analyze  $\frac{d\mu_{\alpha,p}}{d\mu_{1,p}}$  as a function the order  $\alpha$  in Lemma 2;

then use the dominated convergence theorem to obtain the corresponding results for  $\mu_{\alpha,p}$  in Lemma 3.

*Definition 2:* Let *p* be a p.m.f. on  $\mathcal{P}(\mathcal{Y})$  and  $\alpha$  be in  $[0, \infty]$ . Then the order  $\alpha$  density for the prior *p* is

$$\pi_{\alpha,p} \triangleq \frac{\mathrm{d}\mu_{\alpha,p}}{\mathrm{d}\mu_{1,p}}.\tag{9}$$

Note that for any p.m.f. p on  $\mathcal{P}(\mathcal{Y})$ , the order  $\alpha$  density for the prior p is a  $\mathcal{Y}$ -measurable function from  $\mathcal{Y}$  to  $\mathfrak{R}$  by the Radon-Nikodym theorem [17, Th. 5.5.4].

The order  $\alpha$  posteriors defined in the following provides us an alternative way to express  $\pi_{\alpha,p}$  and its derivatives.

Definition 3: Let p be a p.m.f. on  $\mathcal{P}(\mathcal{Y})$  and a be a positive real number. Then for each  $y \in \mathcal{Y}$  the order a posterior  $p_{[\alpha]}$  is a p.m.f. on  $\mathcal{P}(\mathcal{Y})$  given by

$$p_{[\alpha]}(w|y) \triangleq \begin{cases} p(w) \left(\frac{\mathrm{d}w}{\mathrm{d}\mu_{\alpha,p}}\right)^{\alpha} & \text{if } p(w) > 0\\ 0 & \text{else.} \end{cases}$$
(10)

The order  $\alpha$  posterior p.m.f.  $p_{[\alpha]}$  is a  $\mathcal{Y}$ -measurable function for each w. The order one posterior p.m.f.  $p_{[1]}$  is also called the posterior p.m.f., in accordance with the usual terminology.

Lemma 2: For any p.m.f. p on  $\mathcal{P}(\mathcal{Y})$  the following statements hold for  $\mu_{1,p}$ -almost every y.

(a)  $\delta^{\frac{1-\alpha}{\alpha}} \leq \pi_{\alpha,p} \leq 1$  for  $\alpha \in (0, 1]$  and  $1 \leq \pi_{\alpha,p} \leq \delta^{\frac{1-\alpha}{\alpha}}$  for  $\alpha \in [1, \infty)$  where  $\delta = \min_{w:p(w)>0} p(w)$ . Furthermore,

$$\pi_{\alpha,p}(y) = \begin{cases} \prod_{w:p(w)>0} \left(\frac{p_{[1]}(w|y)}{p(w)}\right)^{p(w)} & \alpha = 0\\ \left(\sum_{w} p_{[1]}(w|y)^{\alpha} p(w)^{1-\alpha}\right)^{1/\alpha} & \alpha \in \Re_+\\ \max_{w:p(w)>0} \frac{p_{[1]}(w|y)}{p(w)} & \alpha = \infty. \end{cases}$$

$$p_{[\alpha]}(w|y) = \begin{cases} \frac{p_{[1]}(w|y)^{\alpha} p(w)^{1-\alpha}}{\pi_{\alpha,p}^{\alpha}} & \text{if } p(w) > 0\\ 0 & else. \end{cases}$$

(b)  $\pi_{\alpha,p}$  is a smooth function of  $\alpha$  on  $\Re_+$ . Furthermore, the first two derivatives of  $\pi_{\alpha,p}$  are given by

1

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}\pi_{\alpha,p} = \frac{\pi_{\alpha,p}}{\alpha^2} \sum_{w} p_{[\alpha]}(w|y) \ln \frac{p_{[\alpha]}(w|y)}{p(w)}.$$

$$\frac{\mathrm{d}^2}{\mathrm{d}\alpha^2}\pi_{\alpha,p} = \frac{1-\alpha}{\pi_{\alpha,p}} \left(\frac{\mathrm{d}}{\mathrm{d}\alpha}\pi_{\alpha,p}\right)^2 - \frac{2}{\alpha}\frac{\mathrm{d}}{\mathrm{d}\alpha}\pi_{\alpha,p}$$

$$+ \frac{\pi_{\alpha,p}}{\alpha^3} \sum_{w} p_{[\alpha]}(w|y) \left(\ln \frac{p_{[\alpha]}(w|y)}{p(w)}\right)^2.$$

(c)  $(\pi_{\alpha,p})^{\alpha}$  is log-convex in  $\alpha$  on  $\Re_+$ , i.e. for any  $\beta \in (0, 1)$ and  $\alpha_0, \alpha_1 \in \Re_+$ 

$$(\pi_{\alpha_{\beta},p})^{\alpha_{\beta}} \leq (\pi_{\alpha_{1},p})^{\beta\alpha_{1}}(\pi_{\alpha_{0},p})^{(1-\beta)\alpha_{0}}$$

where  $\alpha_{\beta} = \beta \alpha_1 + (1 - \beta)\alpha_0$ . Furthermore, for  $\alpha_1 \neq \alpha_0$ the inequality is strict iff there exist  $w, \tilde{w} \in \text{supp}(p)$ such that  $\frac{p_{[1]}(w|y)}{p(w)} > \frac{p(\tilde{w}|y)}{p(\tilde{w})} > 0$ . (d) If there exists a w such that  $p_{[1]}(w|y) > p(w)$ , then

(d) If there exists a w such that p<sub>[1]</sub>(w|y) > p(w), then π<sub>α,p</sub>(y) is bounded, continuous, and monotone increasing in α on [0, ∞], else π<sub>α,p</sub>(y) = 1 for all α in [0, ∞].

Lemma 2 establishes the density  $\pi_{\alpha,p}$  as a smooth function  $\mu_{1,p}$ -a.e. and provides expressions for its first two derivatives. These derivatives are  $\mathcal{Y}$ -measurable functions because  $\pi_{\alpha,p}$  and  $p_{[\alpha]}$  are  $\mathcal{Y}$ -measurable. Then using their  $\mu_{1,p}$ -integrals we can define two mappings:

$$\mu'_{\alpha,p}(\mathcal{E}) \triangleq \int_{\mathcal{E}} (\pi'_{\alpha,p}) \mu_{1,p}(\mathrm{d}y) \qquad \forall \mathcal{E} \in \mathcal{Y}, \qquad (11)$$

$$\mu_{\alpha,p}^{\prime\prime}(\mathcal{E}) \triangleq \int_{\mathcal{E}} (\pi_{\alpha,p}^{\prime\prime}) \mu_{1,p}(\mathrm{d}y) \qquad \forall \mathcal{E} \in \mathcal{Y}$$
(12)

where  $\pi'_{\alpha,p}$  and  $\pi''_{\alpha,p}$  are shorthands for  $\frac{d}{d\alpha}\pi_{\alpha,p}$  and  $\frac{d^2}{d\alpha^2}\pi_{\alpha,p}$ .

Note that we have not claimed that either of these mappings is defining a measure for each  $\alpha$ . Lemma 3 given in the following establishes that fact and analyzes the mean measure  $\mu_{\alpha,p}$  as a function of the order  $\alpha$ .

*Lemma 3: For any p.m.f. p on*  $\mathcal{P}(\mathcal{Y})$ *.* 

- (a)  $\mu_{\alpha,p}$  is a continuous function of  $\alpha$  from  $[0,\infty]$  with its usual topology to  $\mathcal{M}_0^+(\mathcal{Y})$  with the total variation topology.
- (b)  $\mu'_{\alpha,p}$  is a continuous function of  $\alpha$  from  $(0, \infty)$  with its usual topology to  $\mathcal{M}_0^+(\mathcal{Y})$  with the total variation topology. Furthermore,  $\frac{d}{d\alpha}\mu_{\alpha,p} = \mu'_{\alpha,p}$  in the sense that

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}\mu_{\alpha,p}(\mathcal{E})\big|_{\alpha=\phi}=\mu'_{\phi,p}(\mathcal{E})\qquad\forall\mathcal{E}\in\mathcal{Y},\,\forall\phi\in(0,\infty).$$

(c)  $\mu_{\alpha,p}''$  is a continuous function of  $\alpha$  from  $(0, \infty)$  with its usual topology to  $\mathcal{M}(\mathcal{Y})$  with the total variation topology. Furthermore,  $\frac{d}{d\alpha}\mu_{\alpha,p}' = \mu_{\alpha,p}''$  in the sense that

$$\frac{\mathrm{d}}{\mathrm{d}a}\mu'_{a,p}(\mathcal{E})\Big|_{a=\phi} = \mu''_{\phi,p}(\mathcal{E}) \qquad \forall \mathcal{E} \in \mathcal{Y}, \, \forall \phi \in (0,\infty).$$

(d)  $\|\mu_{\alpha,p}\|^{\alpha}$  is a log-convex function of  $\alpha$  on  $(0, \infty)$  such that

$$\lim_{\alpha \downarrow 0} \left\| \mu_{\alpha,p} \right\|^{\alpha} = \operatorname{ess\,sup}_{\mu_{1,p}} \sum_{w: p_{[1]}(w|y) > 0} p(w).$$

The log-convexity is strict everywhere on  $(0, \infty)$ , unless there exists a  $\gamma \ge 1$  satisfying  $\mu_{1,p}(\mathcal{A}(p,\gamma)) = 1$  for  $\mathcal{A}(p,\gamma) = \{y : \frac{p_{[1]}(w|y)}{p(w)} = \gamma, \forall w : p_{[1]}(w|y) > 0\}$ . If there exists such a  $\gamma$ , then  $\|\mu_{\alpha,p}\| = \gamma^{\frac{\alpha-1}{\alpha}}$ .

(e)  $\|\mu_{\alpha,p}\|$  is a continuous and nondecreasing function of a from  $[0, \infty]$  to  $[0, |\operatorname{supp}(p)|]$ . If there exist w,  $\widetilde{w}$  in  $\operatorname{supp}(p)$  such that  $w \neq \widetilde{w}$ , then  $\|\mu_{\alpha,p}\|$  is monotone increasing everywhere on  $(0, \infty)$ , else  $\|\mu_{\alpha,p}\| = 1$  for all  $\alpha$  in  $[0, \infty]$ .

Lemma 3 described the properties of the mean measure as a function of the order for a fixed prior. Lemma 4, given in the following, describes the properties of the mean measure as a function of the prior for a fixed order.

Lemma 4: Let  $(\mathcal{Y}, \mathcal{Y})$  be a measurable space.

- (a) If  $\alpha \in [0, 1]$ , then  $\mu_{\alpha,p}$  and  $\|\mu_{\alpha,p}\|$  are convex functions of p from  $\mathcal{P}(\mathcal{P}(\mathcal{Y}))$  to  $\mathcal{M}_0^+(\mathcal{Y})$  and [0, 1], respectively.
- (b) If  $\alpha \in [1,\infty]$ , then  $\mu_{\alpha,p}$  and  $\|\mu_{\alpha,p}\|$  are concave functions of p from  $\mathcal{P}(\mathcal{P}(\mathcal{Y}))$  to  $\mathcal{M}^+(\mathcal{Y})$  and  $[1,\infty)$ , respectively.
- (c) For any  $p_1, p_2 \in \mathcal{P}(\mathcal{P}(\mathcal{Y}))$  such that  $p_1 \neq p_2$ , let  $s_{\wedge}$ ,  $s_1$  and  $s_2$  be  $s_{\wedge} \triangleq 2\frac{p_1 \wedge p_2}{2 - \|p_1 - p_2\|}$ ,  $s_1 \triangleq 2\frac{p_1 - p_1 \wedge p_2}{\|p_1 - p_2\|}$ , and  $s_2 \triangleq 2\frac{p_2 - p_1 \wedge p_2}{\|p_1 - p_2\|}$ . Then  $s_{\wedge}, s_1, s_2 \in \mathcal{P}(\mathcal{P}(\mathcal{Y}))$  and  $p_1 = (1 - \frac{\|p_1 - p_2\|}{2})s_{\wedge} + \frac{\|p_1 - p_2\|}{2}s_1$ ,  $p_2 = (1 - \frac{\|p_1 - p_2\|}{2})s_{\wedge} + \frac{\|p_1 - p_2\|}{2}s_2$ ,  $s_1 \perp s_2$ .

(d) If 
$$\alpha \in (0, 1]$$
, then for any  $p_1, p_2 \in \mathcal{P}(\mathcal{P}(\mathcal{Y}))$  we have

$$\|\mu_{\alpha,p_1} - \mu_{\alpha,p_2}\| \le \frac{1}{\alpha} \|p_1 - p_2\|.$$

Hence  $\mu_{\alpha,p}$  is a Lipschitz continuous function of p for the total variation topology for  $\alpha \in (0, 1]$ .

(e) If  $\alpha \in [1, \infty)$ , then for any  $p_1, p_2 \in \mathcal{P}(\mathcal{P}(\mathcal{Y}))$  we have

$$\|\mu_{\alpha,p_1} - \mu_{\alpha,p_2}\| \le (\frac{1}{2}\|p_1 - p_2\|)^{\frac{1}{\alpha}} \|\mu_{\alpha,s_1} - \mu_{\alpha,s_2}\|.$$

## B. The Rényi Information

Definition 4: Let W be a subset of  $\mathcal{P}(\mathcal{Y})$  and p be a p.m.f. on W. Then the order  $\alpha$  Rényi information for the prior p is

$$I_{\alpha}(p; \mathcal{W}) \triangleq \begin{cases} \underset{\mu_{1,p}}{\operatorname{ess inf}} \ln \frac{1}{\sum_{w} \mathbb{1}_{\{p_{[1]}(w|y)>0\}} p(w)} & \alpha = 0\\ \frac{\alpha}{\alpha-1} \ln \|\mu_{\alpha,p}\| & \alpha \in \mathfrak{R}_{+} \setminus \{1\} \\ \mathbf{E}_{\mu_{1,p}} \left[ \sum_{w} p_{[1]}(w|y) \ln \frac{p_{[1]}(w|y)}{p(w)} \right] & \alpha = 1\\ \ln \|\mu_{\infty,p}\| & \alpha = \infty \end{cases}$$
(13)

Sibson [68] introduced this quantity using the works of Rényi [56] and Csiszár [9], [10]. However, prior to [68] Gallager [20] had introduced  $E_0(\rho, p)$ , which is nothing but a scaled version of the Rényi information, see (3) and (4).

Note that  $I_{\alpha}(p; W)$  has the same value for all W's for which p is in  $\mathcal{P}(W)$ . Hence, in principle, one can use  $I_{\alpha}(p)$  rather than  $I_{\alpha}(p; W)$  to denote the Rényi information. Although this unconventional symbol would be more coherent with the one we use for the mean measure, we refrain from using it for the fear of alienating readers who prefer the customary symbol. Another justification for using the conventional notation is the effect of the richness of W — as measured by  $\sup_{p \in \mathcal{P}(W)} I_{\alpha}(p; W)$ — on the continuity of  $I_{\alpha}(p; W)$  as a function of p, see Lemma 16-(e).

Properties of the Rényi information as a function of the order for fixed prior and as a function of the prior for fixed order are presented in Lemmas 5 and 6, respectively. Proofs of Lemmas 5 and 6 can be found in [48, Appendix E].

Lemma 5: For any subset W of  $\mathcal{P}(\mathcal{Y})$  and p.m.f. p on W,  $I_{\infty}(p; W) \leq \ln |supp(p)|$  and  $I_{\alpha}(p; W)$  is a non-negative continuously differentiable nondecreasing function of  $\alpha$  on  $\Re_+$  such that

$$I_0(\varphi; \mathcal{W}) = \lim_{\alpha \downarrow 0} I_\alpha(\varphi; \mathcal{W}), \qquad (14)$$

$$I_{\infty}(p; \mathcal{W}) = \lim_{\alpha \uparrow \infty} I_{\alpha}(p; \mathcal{W}), \qquad (15)$$

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}I_{\alpha}(p;\mathcal{W}) = \begin{cases} \frac{\alpha}{\alpha-1} \frac{\left\|\mu'_{\alpha,p}\right\|}{\left\|\mu_{\alpha,p}\right\|} - \frac{\ln\left\|\mu_{\alpha,p}\right\|}{(\alpha-1)^{2}} & \alpha \in \mathfrak{N}_{+} \setminus \{1\} \\ \frac{\mu''_{1,p}(\mathfrak{Y}) + 2\left\|\mu'_{1,p}\right\| - \left\|\mu'_{1,p}\right\|^{2}}{2} & \alpha = 1. \end{cases}$$
(16)

If  $\mu_{1,p}(\mathcal{A}(p,\gamma)) = 1$  for some  $\gamma \geq 1$ , then  $I_{\alpha}(p; \mathcal{W}) = \ln \gamma$ for all  $\alpha \in [0, \infty]$ , else  $\frac{d}{d\alpha}I_{\alpha}(p; \mathcal{W}) > 0$  for all  $\alpha \in \mathfrak{R}_+$ , where  $\mathcal{A}(p,\gamma) \triangleq \{y : \frac{p_{[1]}(w|y)}{p(w)} = \gamma \quad \forall w \text{ with positive } p_{[1]}(w|y)\}.$ 

 $\mathcal{A}(p,\gamma) \triangleq \{y: \frac{p_{[1]}(w|y)}{p(w)} = \gamma \quad \forall w \text{ with positive } p_{[1]}(w|y)\}.$ Using the definitions of  $\mu'_{a,p}$  and  $\mu''_{a,p}$ , given in (11) and (12), together with Lemma 2-(b), we get the following two alternative expressions for the derivative of  $I_{\alpha}(p; W)$  with respect to the order on  $\Re_+$ 

$$\frac{\mathrm{d}}{\mathrm{d}\alpha}I_{\alpha}\langle p; \mathcal{W}\rangle$$

$$= \begin{cases}
\frac{1}{(\alpha-1)\alpha}\mathbf{E}_{\varpi_{\alpha}}\left[\ln\frac{p_{[\alpha]}(w|y)}{p(w)} - I_{\alpha}\langle p; \mathcal{W}\rangle\right] & \alpha \neq 1 \\
\frac{1}{2}\mathbf{E}_{\varpi_{1}}\left[\left(\ln\frac{p_{[1]}(w|y)}{p(w)} - I_{1}\langle p; \mathcal{W}\rangle\right)^{2}\right] & \alpha = 1
\end{cases}$$

$$= \begin{cases}
\frac{1}{(\alpha-1)^{2}}\mathbf{E}_{\varpi_{\alpha}}\left[\ln\frac{p_{[\alpha]}(w|y)\pi_{\alpha,p}}{p_{[1]}(w|y)\|\mu_{\alpha,p}\|}\right] & \alpha \neq 1 \\
\frac{1}{2}\mathbf{E}_{\varpi_{1}}\left[\left(\ln\frac{p_{[1]}(w|y)}{p(w)} - I_{1}\langle p; \mathcal{W}\rangle\right)^{2}\right] & \alpha = 1
\end{cases}$$
(17)

where  $\varpi_{\alpha}$  is a probability measure on  $\mathcal{Y} \otimes 2^{\text{supp}(p)}$  whose  $\mathcal{Y}$  marginal is  $\frac{\mu_{\alpha,p}}{\|\mu_{\alpha,p}\|}$  and whose conditional distribution is  $p_{[\alpha]}$ .

The continuity and the convexity properties of the Rényi information in the prior follow from the corresponding properties of the mean measure described in Lemma 4.

Lemma 6: Let W be a subset of  $\mathcal{P}(\mathcal{Y})$ .

- (a) If  $\alpha \in [0, 1)$ , then  $I_{\alpha}(p; W)$  is a non-negative quasiconcave function of p on  $\mathcal{P}(W)$  that is continuous for the total variation topology on  $\mathcal{P}(W)$ .
- (b) If  $\alpha \in [1, \infty]$ , then  $I_{\alpha}(p; W)$  is a non-negative concave function of p on  $\mathcal{P}(W)$ .

Gallager [20, p. 18] and Csiszár [11, Lemma 3.2] established the continuity of  $I_{\alpha}(p; W)$  in p on  $\mathcal{P}(W)$ , for finite W's. For arbitrary W's, however,  $I_{\alpha}(p; W)$  is continuous only for orders in (0, 1); for orders in  $[1, \infty], I_{\alpha}(p; W)$  is continuous in pon  $\mathcal{P}(W)$  iff  $\sup_{p \in \mathcal{P}(W)} I_{\alpha}(p; W)$  is finite, see Lemma 16-(d). The finiteness of  $\sup_{p \in \mathcal{P}(W)} I_{\alpha}(p; W)$  also implies the uniform equicontinuity of the Rényi information, see Lemma 16-(e,f). The discontinuity of various Shannon information measures for countably infinite output sets have previously been pointed out by Ho and Yeung in [35].

## C. The Rényi Divergence

Definition 5: Let w and q be two non-zero finite measures on the measurable space  $(\mathcal{Y}, \mathcal{Y})$ ; then the order  $\alpha$  Rényi divergence between w and q is

$$D_{\alpha}(w \parallel q) \triangleq \begin{cases} -\ln q \left(\frac{dw}{dv} > 0\right) & \alpha = 0\\ \frac{1}{\alpha - 1} \ln \int \left(\frac{dw}{dv}\right)^{\alpha} \left(\frac{dq}{dv}\right)^{1 - \alpha} \nu(dy) & \alpha \in \Re_{+} \setminus \{1\}\\ \int \frac{dw}{dv} \left(\ln \frac{dw}{dv} - \ln \frac{dq}{dv}\right) \nu(dy) & \alpha = 1\\ \ln \operatorname{ess\,sup}_{\nu} \frac{dw}{d\nu} / \frac{dq}{dv} & \alpha = \infty \end{cases}$$

$$(19)$$

where v is any measure satisfying  $w \prec v$  and  $q \prec v$ .

The Rényi divergence is usually defined for probability measures; the inclusion of finite measures allows us to express certain observations, such as Lemma 8 given in the following, more succinctly.<sup>6</sup> Nonetheless, the propositions derived for the usual definition with probability measures suffice for our purposes most of the time. We appropriate all the propositions we need for our analysis, except Lemma 8, from the recent paper of van Erven and Harremoës [18].

The equivalence of Definition 5 and the one used by van Erven and Harremoës [18] for probability measures follows from [18, Ths. 4–6].

Lemma 7 [18, Ths. 3 and 7]: For all  $w, q \in \mathcal{P}(\mathcal{Y})$ ,  $D_{\alpha}(w \parallel q)$  is a nondecreasing and lower semicontinuous function of  $\alpha$  on  $[0,\infty]$  that is continuous on  $[0, (1 \lor \chi_{w,q})]$  where  $\chi_{w,q} \triangleq \sup\{\alpha : D_{\alpha}(w \parallel q) < \infty\}.$ 

Lemma 8 is evident from the definition of Rényi divergence. Lemma 8: Let w, q, v be non-zero finite measures on  $(\mathcal{Y}, \mathcal{Y})$ and  $\alpha$  be an order in  $[0, \infty]$ .

• If  $v \leq q$ , then  $D_{\alpha}(w \parallel q) \leq D_{\alpha}(w \parallel v)$ .

• If  $q = \gamma v$  for  $a \gamma \in \Re_+$ , then  $D_a(w \parallel q) = D_a(w \parallel v) - \ln \gamma$ .

Let *w* and *q* be two probability measures on the measurable space  $(\mathcal{Y}, \mathcal{Y})$  and  $\mathcal{G}$  be a sub- $\sigma$ -algebra of  $\mathcal{Y}$ . Then the identities  $w_{|\mathcal{G}}(\mathcal{E}) = w(\mathcal{E})$  for all  $\mathcal{E} \in \mathcal{G}$  and  $q_{|\mathcal{G}}(\mathcal{E}) = q(\mathcal{E})$ for all  $\mathcal{E} \in \mathcal{G}$  uniquely define probability measures  $w_{|\mathcal{G}}$  and  $q_{|\mathcal{G}}$  on  $(\mathcal{Y}, \mathcal{G})$ . In the following, we denote  $D_{\alpha}(w_{|\mathcal{G}} || q_{|\mathcal{G}})$  by  $D_{\alpha}^{\mathcal{G}}(w|| q)$ .

*Lemma* 9 [18, Th. 9]: For any  $\alpha \in [0, \infty]$ , probability measures w and q on  $(\mathcal{Y}, \mathcal{Y})$  and sub- $\sigma$ -algebra  $\mathcal{G} \subset \mathcal{Y}$ 

$$D_{\alpha}(w \parallel q) \ge D_{\alpha}^{\mathcal{G}}(w \parallel q) \,.$$

Lemma 10 [18, Ths. 3 and 31]: For any  $\alpha \in [0, \infty]$ , probability measures w and q on  $(\mathcal{Y}, \mathcal{Y})$ 

$$D_{\alpha}(w \parallel q) \ge \frac{1 \wedge \alpha}{2} \|w - q\|^2.$$
 (20)

For orders in (0, 1], the bound given in (20) is called the Pinsker's inequality; it has been proved by Csiszár [9] for  $\alpha = 1$  case and by Augustin [5, Lemma 26.5a] and Gilardoni [26] for  $\alpha \in (0, 1)$  case. Furthermore the constant  $\alpha/2$  is the best possible: for any  $\gamma < \alpha/2$  there are probability measures w and q such that  $\gamma ||w - q||^2 > D_{\alpha}(w||q)$ . Determination of best lower bound on the Rényi divergence in terms of the total variation is an interesting and important problem but it is beyond the scope of the current manuscript.

Remark 1: Kullback [40], [41] bounded  $D_1(w \parallel q)$  from below by  $||w - q||^2/2 + ||w - q||^4/36$ . Hence, Pinsker's inequality is tight only for  $||w - q|| \approx 0$ . Vajda [73] established  $D_1(w||q) \ge \ln(\frac{2+||w-q||}{2-||w-q||}) - \frac{2||w-q||}{2+||w-q||}$ . Vajda's inequality is tight not only for  $||w - q|| \approx 0$  but also for  $||w - q|| \approx 2$ . Fedotov et al. [19] determined the tight lower bound on  $D_1(w \parallel q)$  in terms of  $\|w - q\|$  in a parametric form. Gilardoni [24], [25] proved an equivalent result for f-divergences for twice differentiable f's. Gilardoni's result implies tight bounds for Rényi divergences, which are recently derived in a more explicit form by Sason [59, Proposition 1]. The core observation in the derivation of tight Vajda's inequalities is the sufficiency of the probability measures on binary alphabets. Guntuboyina et al. [27] have recently generalized this observation considerably and explained how one can determine tight bounds on an f-divergence when its arguments are constrained in terms of other f-divergences. Recall that the total variation distance is the *f*-divergence for f(x) = |x - 1|.

Lemma 11 [18, Th. 12]: For any order  $\alpha \in [0, \infty]$ , the order  $\alpha$  Rényi divergence is convex in its second argument for probability measures, i.e. for all  $w, q_0, q_1 \in \mathcal{P}(\mathcal{Y})$  and

<sup>&</sup>lt;sup>6</sup>It is also convenient while studying the concept of the Rényi-Gallager information and capacity, see [47] and [52].

 $\beta \in (0, 1)$  we have

$$D_{\alpha}(w \parallel q_{\beta}) \leq \beta D_{\alpha}(w \parallel q_1) + (1 - \beta) D_{\alpha}(w \parallel q_0)$$

where  $q_{\beta} = \beta q_1 + (1 - \beta) q_0$ .

Lemma 12 [18, Th. 13]: For any order  $\alpha \in [0, \infty]$ , the order a Rényi divergence is jointly quasi-convex in its arguments for probability measures, i.e. for all  $w_0$ ,  $w_1$ ,  $q_0$ ,  $q_1$ in  $\mathcal{P}(\mathcal{Y})$  and  $\beta \in (0, 1)$  we have

$$D_{\alpha}(w_{\beta} \parallel q_{\beta}) \leq D_{\alpha}(w_1 \parallel q_1) \vee D_{\alpha}(w_0 \parallel q_0)$$

where  $w_{\beta} = \beta w_1 + (1 - \beta) w_0$  and  $q_{\beta} = \beta q_1 + (1 - \beta) q_0$ .

Lemma 13 [18, Th. 15]: For any order  $\alpha \in (0, \infty]$ ,  $D_{\alpha}(w \parallel q)$  is a lower semicontinuous function of the pair of probability measures (w, q) in the topology of setwise convergence.

The preceding lemmas discuss only the aspects of the Rényi divergence that are useful for our discussion. A more comprehensive discussion can be found in [18].

#### D. The Rényi Mean

We have defined the Rényi information using a closed form expression. However, the original definition of the Rényi information by Sibson is in terms of an optimization of the Rényi divergence over a set of probability measures. These two definitions are equivalent, as it has already been shown by Sibson [68, Th. 2.2]. In the following, we establish this equivalence and briefly discuss an alternative definition of the Rényi information related to the aforementioned characterization in terms of the Rényi divergence.

Definition 6: Let p be a p.m.f. on  $\mathcal{P}(\mathcal{Y})$ ; then the order a Rényi mean for prior p is

$$q_{\alpha,p} \triangleq \begin{cases} \frac{e^{-D_{1}\left(p_{[0]} \| p_{[1]}\right)} \mathbb{1}_{\{\vartheta_{p}(y) = \bar{\vartheta}_{p}\}} \mu_{1,p}}{\int e^{-D_{1}\left(p_{[0]} \| p_{[1]}\right)} \mathbb{1}_{\{\vartheta_{p}(y) = \bar{\vartheta}_{p}\}} \mu_{1,p}(\mathrm{d}y)} & \alpha = 0\\ \frac{\mu_{\alpha,p}}{\| \mu_{\alpha,p} \|} & \alpha \in (0,\infty] \end{cases}$$
(21)

where  $\vartheta_p(y) \triangleq \sum_{w} p(w) \mathbb{1}_{\{p_{[1]}(w|y)>0\}}, \bar{\vartheta}_p \triangleq \operatorname{ess\,sup}_{\mu_{1,p}} \vartheta_p$ , and  $p_{[0]}(w|y) \triangleq \frac{p(w)\mathbb{1}_{\{p_{[1]}(w|y)>0\}}}{\sum_{\mu} p(u)\mathbb{1}_{\{p_{(1)}(w|y)>0\}}}.$ Then the following identity can be confirmed by substitution

using (19): For any  $\alpha$  in  $(0, \infty]$ , p in  $\mathcal{P}(\mathcal{W})$ , and q in  $\mathcal{P}(\mathcal{Y})$ ,

$$D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q) = D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q_{\alpha,p}) + D_{\alpha}(q_{\alpha,p} \| q).$$
(22)

This identity was first pointed out by Sibson in [68, p. 153], then by others [13, eq. (12)], [33, eq. (43)], [54, eq. (38)], [65, Lemma 3], and [74, eq. (52)]. For  $\alpha = 1$  case, it had been used by Topsøe [71], even before Sibson [68] and Topsøe [72].

On the other hand, one can also confirm by substitution that  $I_{\alpha}(p; W) = D_{\alpha}(p \otimes W || p \otimes q_{\alpha, p})$  for all positive values of  $\alpha$ . These two observations lead to the alternative characterization of the order  $\alpha$  Rényi information in terms of the order  $\alpha$ Rényi divergence presented in the following lemma, which is valid for all non-negative orders.

Lemma 14: Let  $\mathcal{W}$  be a subset of  $\mathcal{P}(\mathcal{Y})$ , p be a p.m.f. on  $\mathcal{W}$ , and  $\alpha$  be an order in  $[0, \infty]$ ; then

$$I_{\alpha}(p; \mathcal{W}) = D_{\alpha}(p \circledast \mathcal{W} || p \otimes q_{\alpha, p})$$
<sup>(23)</sup>

$$= \inf_{q \in \mathcal{P}(\mathcal{Y})} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q)$$
(24)

$$= \inf_{q \in \mathcal{P}(\mathcal{Y})} D_{\alpha} \left( \mu_{\alpha, p} \| q \right) \quad \alpha \in (0, \infty] \setminus \{1\} \quad (25)$$

where  $p \circledast W$  is the probability measure on  $2^{\operatorname{supp}(p)} \otimes \mathcal{Y}$  whose marginal distribution on supp(p) is p and whose conditional distribution is w.

Proof of Lemma 14 is presented in [48, Appendix F]. For any positive order  $\alpha$  and prior p, the only probability measure q satisfying  $D_{\alpha}(p \otimes \mathcal{W} || p \otimes q) = I_{\alpha}(p; \mathcal{W})$  is  $q_{\alpha,p}$  as a result of (22) and Lemmas 10, 14. In other words, the order  $\alpha$  Rényi mean for prior p is the unique minimizer for the infimum given in (24) for positive orders  $\alpha$ . For  $\alpha = 0$ , the order zero Rényi mean is still a minimizer by Lemma 14 but it is not necessarily the unique minimizer. Any probability measure q that is absolutely continuous in the  $q_{0,p}$  satisfies  $D_0(p \circledast \mathcal{W} \| p \otimes q) = I_0(p; \mathcal{W}).$ 

The definition of Rényi information we have adopted is not the only definition of Rényi information. The following definition is first proposed by Augustin [5, §34] and later popularized by Csiszár [13]

$$I_{\alpha}^{c}(p; \mathcal{W}) \triangleq \inf_{q \in \mathcal{P}(\mathcal{Y})} \sum_{w} p(w) D_{\alpha}(w \| q).$$
(26)

Unlike the definition we have adopted, the one given in (26) does not have an equivalent closed form expression. But for any finite positive order  $\alpha$ , the infimum in (26) has a unique minimizer, which is a fixed point of an operator defined using  $\alpha$  and p, [47]. These properties were first proved by Augustin for orders between zero and one in [5]. Thus we have called the quantity defined in (26), the order  $\alpha$  Augustin information in [52]. We present a more detailed discussion of the properties of the Augustin information and its relation to the Rényi information in [47].

Arimoto [3] proposed a third definition for the Rényi information. Recently, Verdú [74] has provided a discussion of the Rényi entropy and these three definitions of the Rényi information.

#### III. THE RÉNYI CAPACITY

Definition 7: Let  $\alpha$  be an order in  $[0, \infty]$  and W be a subset of  $\mathcal{P}(\mathcal{Y})$ ; then the order  $\alpha$  Rényi capacity of  $\mathcal{W}$  is

$$C_{\alpha,\mathcal{W}} \triangleq \sup_{p \in \mathcal{P}(\mathcal{W})} I_{\alpha}(p;\mathcal{W}).$$
 (27)

Unlike the Rényi information, the Rényi capacity is not a quantity that is introduced or discussed by Sibson [68]. In the spirit of his earlier work on f-divergences [11], Csiszár introduced it in [13]. Shannon, Gallager, and Berlekamp had introduced a 'capacity', i.e.  $E_0(\rho, W)$ , using  $E_0(\rho, p)$  in [63], prior to either work.  $E_0(\rho, W)$  is a scaled version of the Rényi capacity; in particular  $E_0(\rho, W) = \rho C_{\frac{1}{1-\epsilon}, W}$  for all  $\rho > -1$ .

Using the alternative characterization of the Rényi information given in (24), we get the following expression for the order  $\alpha$  Rényi capacity for all  $\alpha$  in  $[0, \infty]$ 

$$C_{\alpha,\mathcal{W}} = \sup_{p \in \mathcal{P}(\mathcal{W})} \inf_{q \in \mathcal{P}(\mathcal{Y})} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q).$$
(28)

For finite orders the Rényi capacity does not have a closed form expression. The supremum given in the definition of the Rényi capacity need not to be finite, see [48, Examples 6 and 7]. Even when the supremum is finite it might not be achieved by any prior, i.e. there are W's for which  $I_{\alpha}(p; W) < C_{\alpha, W}$  for all  $p \in \mathcal{P}(W)$ , see [48, Examples 2 and 4]. When the supremum is achieved, the optimal prior might not be unique, i.e. there are W's for which  $I_{\alpha}(p_2; W) = C_{\alpha, W}$  for  $p_1 \neq p_2$  both of which are in  $\mathcal{P}(W)$ , see [48, Example 3]. These subtleties, however, do not constitute a serious impediment for analyzing the Rényi capacity.

In §III-A, we analyze the Rényi capacity as a function of the order. In §III-B, we determine necessary and sufficient conditions for the finiteness of the Rényi capacity and investigate the implications of the finiteness of the Rényi capacity on the continuity of the mean measure and the Rényi information.

#### A. The Rényi Capacity as a Function of the Order

We are interested in characterizing the behavior of the Rényi capacity as a function of the order because the operational significance of the Rényi capacity —at least for the channel coding problem and the sphere packing bound— is not through its value at a specific order but through its behavior as a function of the order. Parts (a,c,d,e,f) of Lemma 15 characterize the behavior of the Rényi capacity for an arbitrary W as a function of the order. In our analysis relying on the Rényi capacity some of our results might be valid only for countable or finite W's rather than arbitrary W's. Parts (b,g) of Lemma 15 are useful in such situations.<sup>7</sup> See the proof of [50, Corollary 2] for such a situation for the Augustin capacity. *Lemma 15: Let W be a subset of*  $\mathcal{P}(\mathcal{Y})$ .

- (a)  $C_{\alpha,W}$  is nondecreasing and lower semicontinuous in  $\alpha$  on  $[0, \infty]$ .
- (b) There exists a countable subset W' of W satisfying  $C_{\alpha,W} = C_{\alpha,W}$  for all  $\alpha \in [0, \infty]$ .
- (c)  $\frac{1-\alpha}{\alpha}C_{\alpha,W}$  is nonincreasing and continuous in  $\alpha$  on (0, 1)and  $C_{\alpha,W}$  is continuous in  $\alpha$  on (0, 1].
- (d)  $(\alpha 1)C_{\alpha,W}$  is convex in  $\alpha$  on  $(1, \infty)$ .
- (e) If  $C_{\eta,W} < \infty$  for an  $\eta \in (0, 1)$ , then  $C_{\alpha,W}$  is finite for all  $\alpha \in [0, 1)$ .
- (f) If  $C_{\eta,W} < \infty$  for an  $\eta \in (0,\infty]$ , then  $C_{\alpha,W}$  is nondecreasing and continuous<sup>8</sup> in  $\alpha$  on  $(0,\eta]$ .
- (g) If  $C_{\eta,W} < \infty$  for an  $\eta \in (0, \infty]$ , then  $\forall \epsilon > 0, \exists$  a finite subset W' of W such that  $C_{\alpha,W} > C_{\alpha,W} \epsilon$  for all  $\alpha \in [\epsilon, \eta]$ .

The Rényi information  $I_{\alpha}(p; W)$  is continuous in  $\alpha$  for any p in  $\mathcal{P}(W)$  by Lemma 5, however the Rényi capacity  $C_{\alpha, W}$  is not necessarily continuous in  $\alpha$ . Yet, if the Rényi capacity

 $C_{\alpha,W}$  is not continuous in  $\alpha$  on  $(0, \infty]$ , then it has a very specific shape as a result of Lemma 15: there exists a  $\phi \in [1, \infty)$  such that  $C_{\alpha,W}$  is bounded and continuous on  $(0, \phi]$  and infinite on  $(\phi, \infty]$ . In order to see why, first note that if  $C_{1/2,W} = \infty$ , then  $C_{\alpha,W} = \infty$  for all  $\alpha$  in  $(0, \infty]$  by Lemma 15-(a,e) and  $C_{\alpha,W}$  is continuous on  $(0, \infty]$ . On the other hand, if  $C_{\infty,W} < \infty$ , then  $C_{\alpha,W}$  can fail to be continuous on  $(0, \infty]$  by Lemma 15-(f). Hence,  $C_{\alpha,W}$  can fail to be continuous on  $(0, \infty]$  only when  $C_{1/2,W} < \infty$  and  $C_{\infty,W} = \infty$ . Let  $\chi_W$  be the set of all orders  $\alpha$  for which  $C_{\alpha,W}$  is finite, i.e.

$$\chi_{\mathcal{W}} \triangleq \{ \alpha \in \mathfrak{R}_+ : C_{\alpha, \mathcal{W}} < \infty \}.$$

 $\chi_W$  is either of the form  $(0, \phi)$  for a  $\phi \in [1, \infty]$  or of the form  $(0, \phi]$  for a  $\phi \in [1, \infty)$  because  $C_{a,W}$  is nondecreasing by Lemma 15-(a) and finite on (0, 1) by Lemma 15-(e). If  $\chi_W = (0, \phi)$  for some  $\phi \in [1, \infty]$ , then  $C_{a,W}$  is continuous on  $(0, \phi]$  by Lemma 15-(a,f),  $C_{a,W}$  is infinite on  $[\phi, \infty]$  by the hypothesis, and hence  $C_{a,W}$  is continuous on  $(0, \infty]$  by the pasting lemma [46, Th. 18.3]. — [48, Example 6] provides a W for each  $\phi \in (1, \infty)$  such that  $\chi_W = (0, \phi)$ .— Thus unless  $\chi_W = (0, \phi]$  for some  $\phi \in [1, \infty)$ ,  $C_{a,W}$  is continuous on  $(0, \infty]$ . If  $\chi_W = (0, \phi]$ , then  $C_{a,W}$  is bounded and continuous on  $(0, \phi]$  and infinite on  $(\phi, \infty]$ . Hence the Rényi capacity has a unique discontinuity on  $(0, \infty]$ , which is at  $\phi$ . — [48, Example 7] provides a W for each  $\phi \in [1, \infty)$  such that  $C_{a,W}$  has its unique discontinuity at  $\phi$ .—

Proof of Lemma 15:

- (a) The pointwise supremum of a family of nondecreasing (lower semicontinuous) functions is nondecreasing (lower semicontinuous). Then C<sub>α,W</sub> is nondecreasing and lower semicontinuous in α on [0, ∞] because C<sub>α,W</sub> is the pointwise supremum of the family {I<sub>α</sub>(p; W)}<sub>p∈P(W)</sub> and I<sub>α</sub>(p; W) is nondecreasing and continuous in α for each p∈P(W) by Lemma 5.
- (b) The Rényi capacity is a nondecreasing and lower semicontinuous function of the order by part (a). Then

$$C_{\eta,\mathcal{W}} = \sup_{\alpha \in (0,\eta) \cap \mathbb{Q}} C_{\alpha,\mathcal{W}} \quad \forall \eta \in (0,\infty].$$

Consequently,  $C_{\alpha,W} = C_{\alpha,W}$  for all  $\alpha$  in  $[0, \infty]$  if  $C_{\alpha,W} = C_{\alpha,W}$  for all  $\alpha \in \mathbb{Q}_{\geq 0}$ . Choose a sequence of p.m.f.'s  $\{p^{(\alpha,l)}\}_{l \in \mathbb{Z}_+}$  satisfying  $I_{\alpha}(p^{(\alpha,l)};W) \uparrow C_{\alpha,W}$  for each  $\alpha \in \mathbb{Q}_{\geq 0}$ . Let W' be  $\bigcup_{\alpha \in \mathbb{Q}_{\geq 0}} \bigcup_{l \in \mathbb{Z}_+} \operatorname{supp}(p^{(\alpha,l)})$ . Then  $C_{\alpha,W} = C_{\alpha,W}$  for all  $\alpha \in \mathbb{Q}_{\geq 0}$ ; hence for all  $\alpha$  in  $[0, \infty]$ . W' is countable because countable union of countable sets is countable.

(c)  $\|\mu_{\alpha,p}\|$  is nondecreasing and continuous in  $\alpha$ , by Lemma 3-(e). Furthermore, the definitions of  $I_{\alpha}(p; W)$ and  $C_{\alpha, W}$  imply

$$\frac{1-\alpha}{\alpha}C_{\alpha,\mathcal{W}} = \sup_{p\in\mathcal{P}(\mathcal{W})} \ln \frac{1}{\|\mu_{\alpha,p}\|} \quad \forall \alpha \in (0,1).$$

Then  $\frac{1-\alpha}{\alpha}C_{\alpha,W}$  is nonincreasing and lower semicontinuous in  $\alpha$  on (0, 1) because the pointwise supremum of a family of nonincreasing (lower semicontinuous) functions is nonincreasing (lower semicontinuous). Thus  $\frac{1-\alpha}{\alpha}C_{\alpha,W}$  and  $C_{\alpha,W}$  are both continuous from the right on (0, 1). On the other hand  $C_{\alpha,W}$  and  $\frac{1-\alpha}{\alpha}C_{\alpha,W}$  are both continuous from the left on (0, 1) because  $C_{\alpha,W}$  is

<sup>&</sup>lt;sup>7</sup>As pointwise statements, i.e. as statements for a given order, Lemma 15-(b,g) follow trivially from the definition of the Rényi capacity. They are non-trivial only because their assertions hold for all orders for the same W'.

<sup>&</sup>lt;sup>8</sup>We are unable to establish the continuity of  $C_{\alpha, \mathcal{W}}$  at  $\alpha = 0$  for arbitrary  $\mathcal{W}$ . For finite  $\mathcal{W}$ , Sion's minimax theorem implies the continuity of  $C_{\alpha, \mathcal{W}}$  at  $\alpha = 0$ , see Lemma 16-(g).

nondecreasing and lower semicontinuous on (0, 1) by part (a). Consequently,  $C_{\alpha,\mathcal{W}}$  and  $\frac{1-\alpha}{\alpha}C_{\alpha,\mathcal{W}}$  are both continuous on (0, 1). Furthermore,  $C_{\alpha,\mathcal{W}}$  is continuous on (0, 1] because  $C_{\alpha,\mathcal{W}}$  is nondecreasing and lower semicontinuous by part (a).

(d)  $\|\mu_{\alpha,p}\|^{\alpha}$  is log-convex in  $\alpha$  by Lemma 3-(d). On the other hand, by the definitions of  $I_{\alpha}(p; W)$  and  $C_{\alpha, W}$  we have

$$(\alpha - 1)C_{\alpha, \mathcal{W}} = \sup_{p \in \mathcal{P}(\mathcal{W})} \alpha \ln \|\mu_{\alpha, p}\| \quad \forall \alpha \in (1, \infty).$$

Then  $(\alpha - 1)C_{\alpha,W}$  is convex in  $\alpha$  because the pointwise supremum of a family of convex functions is convex.

- (e) If C<sub>η,W</sub> is finite, then so is C<sub>α,W</sub> for all α in [0, η] because C<sub>α,W</sub> is nondecreasing in α by part (a). Furthermore, if C<sub>η,W</sub> is finite, then so is C<sub>α,W</sub> for all α in [η, 1) because 1-α/α C<sub>α,W</sub> is nonincreasing in α on (0, 1) by part (c).
- (f)  $C_{\alpha, W}$  is continuous in  $\alpha$  on (0, 1] by part (c). Thus we only need to prove the claim for the case when  $\eta > 1$ on [1,  $\eta$ ]. We prove the continuity of  $C_{\alpha, \mathcal{W}}$  in  $\alpha$  first on  $(1, \eta]$ , and then from the right at  $\alpha = 1$ . If  $C_{\eta, W}$ is finite for an  $\eta$  in  $(1, \infty)$ , then  $(\alpha - 1)C_{\alpha, W}$  is finite and convex in  $\alpha$  on  $[1, \eta]$  by parts (a) and (d). Then the continuity of  $(\alpha - 1)C_{\alpha,\mathcal{W}}$ , and hence the continuity of  $C_{\alpha,\mathcal{W}}$ , in  $\alpha$  on  $(1,\eta)$  follows from [17, Th. 6.3.3]. On the other hand  $C_{\alpha, \mathcal{W}}$  is continuous from the left because  $C_{\alpha,\mathcal{W}}$  is nondecreasing and lower semicontinuous in  $\alpha$ by part (a). Hence,  $C_{\alpha,W}$  is continuous in  $\alpha$  on  $(1, \eta]$ . If  $C_{\infty,\mathcal{W}}$  is finite, then  $C_{\eta,\mathcal{W}}$  is finite for all  $\eta \in \Re_+$ by part (a) and  $C_{\alpha, W}$  is continuous in  $\alpha$  on  $\Re_+$  because the continuity of a function on a collection of open set implies its continuity on their union, [46, Th. 18.2]. This implies the continuity of  $C_{\alpha, W}$  on  $(0, \infty]$  because  $C_{\alpha, W}$ is nondecreasing and lower semicontinuous in  $\alpha$  by part (a).

For proving the continuity of  $C_{\alpha,W}$  from the right at  $\alpha = 1$ , we first prove that  $\{I_{\alpha}(p;W)\}_{p \in \mathcal{P}(W)}$  is equicontinuous from the right at  $\alpha = 1$ . The definitions of  $\mu'_{\alpha,p}$ and  $I_{\alpha}(p;W)$  given in (11) and (13) and Lemma 2-(b) imply

$$I_{\alpha}(p; \mathcal{W}) - I_{1}(p; \mathcal{W}) = \frac{\alpha \ln \|\mu_{\alpha, p}\| - (\alpha - 1) \|\mu'_{1, p}\|}{\alpha - 1}$$

for all  $\alpha$  in  $(1, \eta]$  and p in  $\mathcal{P}(\mathcal{W})$ . The expression in the numerator is differentiable in  $\alpha$  because  $\|\mu_{\alpha,p}\|$  is differentiable by Lemma 3-(b). Furthermore,  $\frac{d}{d\alpha}\|\mu_{\alpha,p}\| = \|\mu'_{\alpha,p}\|$  by Lemma 3-(b) and the numerator is zero at  $\alpha = 1$ . Then by the mean value theorem [57, Th. 5.10], there exists a  $\phi \in (1, \alpha)$  such that

$$I_{\alpha}(p; \mathcal{W}) - I_{1}(p; \mathcal{W}) = \ln \|\mu_{\phi, p}\| + \phi \frac{\|\mu'_{\phi, p}\|}{\|\mu_{\phi, p}\|} - \|\mu'_{1, p}\|.$$

The expression on the right hand side is differentiable in  $\phi$  because  $\frac{d}{d\phi} \|\mu_{\phi,p}\| = \|\mu'_{\phi,p}\|$  and  $\frac{d}{d\phi} \|\mu'_{\phi,p}\| = \mu''_{\phi,p}(\mathcal{Y})$  by Lemma 3-(b,c). On the other hand,  $\|\mu_{\phi,p}\| > 0$  for  $\phi \in \mathfrak{R}_+$  and  $\|\mu_{1,p}\| = 1$  by Lemma 1-(a). Then the expression on the right hand side is zero at  $\phi = 1$ . Hence, using the mean value theorem [57, Th. 5.10] once again we can conclude that there exists a  $\beta \in (1, \phi)$  such that

$$\frac{I_{a}(p;\mathcal{W}) - I_{1}(p;\mathcal{W})}{\phi - 1} = 2 \frac{\left\| \mu'_{\beta,p} \right\|}{\left\| \mu_{\beta,p} \right\|} + \beta \frac{\mu''_{\beta,p}(\mathcal{Y})}{\left\| \mu_{\beta,p} \right\|} - \beta \frac{\left\| \mu'_{\beta,p} \right\|^{2}}{\left\| \mu_{\beta,p} \right\|^{2}}.$$
 (29)

On the other hand using the definition of  $\mu_{\alpha,p}''$  given in (12) together with Lemma 2-(b) and  $\beta > 1$  we get,

$$\frac{\mu_{\beta,p}''(\mathcal{Y})}{\|\mu_{\beta,p}\|} \le \mathbf{E}_{q_{\beta,p}} \left[ \sum_{w} \frac{p_{[\beta]}(w|y)}{\beta^3} \ln^2 \frac{p_{[\beta]}(w|y)}{p(w)} \right] - \frac{2}{\beta} \frac{\mu_{\beta,p}'}{\|\mu_{\beta,p}\|}$$

Then using Lemma 2-(a) and (29) we get

$$\frac{I_{a}(p;\mathcal{W})-I_{1}(p;\mathcal{W})}{\phi-1} \leq \mathbf{E}_{q_{\beta,p}} \left[ \sum_{w} \frac{p_{[\beta]}(w|y)}{\beta^{2}} \ln^{2} \frac{p_{[\beta]}(w|y)}{p(w)} \right]$$
$$= \mathbf{E}_{q_{\beta,p}} \left[ \sum_{w} p(w) \left[ \frac{p_{[1]}(w|y)}{p(w)\pi_{\beta,p}} \right]^{\beta} \ln^{2} \frac{p_{[1]}(w|y)}{p(w)\pi_{\beta,p}} \right].$$

Recall that  $x^{\beta} \ln^2 x \leq (\frac{2}{\beta e})^2$  for all  $x \in [0, 1]$  and  $\beta > 0$  and  $\ln^2 x \leq (\frac{2}{\epsilon e})^2 x^{\epsilon}$  for all  $x \geq 1$  and  $\epsilon > 0$ . Thus

$$\frac{I_{a}(p;\mathcal{W}) - I_{1}(p;\mathcal{W})}{\phi - 1} \leq \mathbf{E}_{q_{\beta,p}} \left[ \left(\frac{2}{\beta e}\right)^{2} + \left(\frac{2}{\epsilon e}\right)^{2} \left(\frac{\pi_{\beta + \epsilon, p}}{\pi_{\beta, p}}\right)^{\beta + \epsilon} \right]$$

Since  $(\pi_{\alpha,p})^{\alpha}$  is log-convex in  $\alpha$  by Lemma 2-(c),

$$(\pi_{\beta+\epsilon,p})^{\beta+\epsilon} \le (\pi_{\beta,p})^{\beta+\epsilon-1} \pi_{\frac{\beta}{1-\epsilon},p} \quad \forall \epsilon \in (0,1), \beta > 1.$$

Then using the fact that  $\|\mu_{\beta,p}\| \ge \|\mu_{1,p}\| = 1$  we get

$$\frac{I_{\alpha}(p;\mathcal{W}) - I_{1}(p;\mathcal{W})}{\phi - 1} \leq \left[ \left(\frac{2}{\beta e}\right)^{2} + \left(\frac{2}{\epsilon e}\right)^{2} \left\| \mu_{\frac{\beta}{1 - \epsilon}, p} \right\| \right].$$

Note that  $\|\mu_{\beta/1-\epsilon,p}\| \leq \|\mu_{\alpha/1-\epsilon,p}\|$  because  $\|\mu_{\alpha,p}\|$  is nondecreasing in  $\alpha$  by Lemma 3-(e). Then the definition of Rényi information,  $\beta > 1$ , and  $\phi \in (1, \alpha)$  imply for any  $\epsilon \in (0, \frac{\eta-1}{\eta}), \alpha \in [1, (1-\epsilon)\eta]$  and  $p \in \mathcal{P}(\mathcal{W})$  that

$$I_{\alpha}(p; \mathcal{W}) - I_{1}(p; \mathcal{W}) \leq \frac{8(\alpha-1)}{\epsilon^{2}e^{2}} e^{\frac{\alpha-1+\epsilon}{\alpha}I_{\frac{\alpha}{1-\epsilon}}(p; \mathcal{W})}$$
$$\leq \frac{8(\alpha-1)}{\epsilon^{2}e^{2}} e^{\frac{\eta-1}{\eta}I_{\eta}(p; \mathcal{W})}.$$
(30)

Then for any  $\epsilon \in (0, \frac{\eta-1}{\eta})$  and  $\alpha \in [1, (1-\epsilon)\eta]$  we can bound  $C_{\alpha, \mathcal{W}}$  as follows

$$C_{\alpha,\mathcal{W}} \leq \sup_{p \in \mathcal{P}(\mathcal{W})} I_1(p;\mathcal{W}) + \frac{8(\alpha-1)}{\epsilon^2 e^2} e^{\frac{\eta-1}{\eta} I_\eta(p;\mathcal{W})}$$
  
$$\leq C_{1,\mathcal{W}} + \frac{8(\alpha-1)}{\epsilon^2 e^2} e^{\frac{\eta-1}{\eta} C_{\eta,\mathcal{W}}}.$$

Hence,  $C_{\alpha,W}$  is continuous from the right at  $\alpha = 1$  if  $C_{\eta,W} < \infty$  for an  $\eta > 1$ .

(g) Let us first consider  $\eta \in \mathfrak{R}_+$  case and construct a sequence  $\{W_i\}_{i \in \mathbb{Z}_+}$  of finite subset of W, such that  $C_{\alpha, \mathcal{W}_i} \uparrow C_{\alpha, \mathcal{W}}$  for all  $\alpha \in (0, \eta]$ . Choose a  $p^{(i, j)}$  in  $\mathcal{P}(W)$  such that  $I_{j2^{-i}}(p^{(i, j)}; \mathcal{W}) \geq C_{j2^{-i}}, \mathcal{W} - 2^{-i}$  for each  $i \in \mathbb{Z}_+$  and non-negative integer j not exceeding  $2^i \eta$ . Let  $W_0$  be the empty set and  $W_i$  be  $W_{i-1} \cup_{j=0}^{\lfloor 2^i \eta \rfloor} \operatorname{supp}(p^{(i, j)})$  for each  $i \in \mathbb{Z}_+$ . Then

$$\begin{split} C_{\alpha,\mathcal{W}_{l}} &\geq C_{\alpha,\mathcal{W}_{l-1}} & \forall \alpha \in [0,\infty], \ \iota \in \mathbb{Z}_{+} \\ C_{\alpha,\mathcal{W}_{l}} &\geq C_{\alpha,\mathcal{W}} - 2^{-\iota} & \forall \alpha \in \{\frac{0}{2^{\iota}}, \dots, \frac{\lfloor \eta 2^{\iota} \rfloor}{2^{\iota}}\}, \ \iota \in \mathbb{Z}_{+}. \end{split}$$

Then  $C_{\alpha,W_i} \uparrow C_{\alpha,W}$  for all dyadic rational numbers  $\alpha$ less than  $\eta$ . Therefore  $C_{\alpha,W_i} \uparrow C_{\alpha,W}$  for all  $\alpha \in [0, \eta]$ because the Rényi capacity is nondecreasing and lower semicontinuous. Since  $C_{\eta,W_i} \leq C_{\eta,W} < \infty$ ,  $C_{\alpha,W_i}$ 's and  $C_{\alpha,W}$  are continuous in  $\alpha$  on  $(0, \eta]$ by part (f). Then as a result of Dini's theorem [17, Th. 2.4.10],  $\{C_{\alpha,W_i}\}_{i\in\mathbb{Z}_+}$  converges to  $C_{\alpha,W}$  uniformly on  $[\epsilon, \eta]$ , i.e. for all  $\varepsilon > 0$ , there exists an  $\iota$  such that  $\sup_{\alpha \in [\epsilon, \eta]} |C_{\alpha,W} - C_{\alpha,W_j}| < \varepsilon$  for all  $j > \iota$ . For  $\eta = \infty$  case, let  $\kappa_i$  be the smallest integer satisfying  $C_{\infty,W} \leq C_{\kappa_i 2^{-\iota},W} + 2^{-\iota}$  for each  $\iota \in \mathbb{Z}_+$ . We employ the construction described above for j's not exceeding  $\kappa_i$  rather than j's not exceeding  $\lfloor 2^{\iota} \eta \rfloor$ .

## B. Finiteness of the Rényi Capacity

If W is a finite set, then  $\mathcal{P}(W)$  is compact for the total variation topology and various results relying on the compactness can be invoked while analyzing the Rényi information. For example, if W is finite, then the compactness of  $\mathcal{P}(W)$  and Sion's minimax theorem imply the continuity of the Rényi capacity in the order on  $[0, \infty]$ , see Lemma 16-(g). When W is an infinite set, however,  $\mathcal{P}(W)$  is not compact. The finiteness of the Rényi capacity emerges as a shrewd substitute for the compactness of  $\mathcal{P}(W)$  that allows us to assert the continuity of the Rényi information, see Lemma 16-(e,f).

Lemma 16-(a-d) characterize the finiteness of the order  $\alpha$ Rényi capacity in terms of the properties of the order  $\alpha$  mean measure or Rényi information. These equivalent conditions might be easier to confirm or reject for certain W's. The equicontinuity results given in Lemma 16-(e,f) imply that if  $\gamma_1 \leq I_\alpha(p; W) \leq \gamma_2$  for all  $p \in \mathcal{A}$  for some  $\alpha$  in  $(0, \eta)$  and  $\gamma_1$  and  $\gamma_2$  in  $[0, C_{\eta, W}]$ , then for any  $\epsilon > 0$  there exists a  $\delta > 0$  such that  $\gamma_1 - \epsilon \leq I_\phi(s; W) \leq \gamma_2 + \epsilon$  for all  $\phi$  in  $[\alpha - \delta, \alpha + \delta]$  and s in  $\mathcal{P}(W)$  satisfying  $\inf_{p \in \mathcal{A}} ||p - s|| \leq \delta$ . This observation (or its variants, which can be obtained by employing either part (e) or (f) on its own) might be helpful when we are trying to bound the Rényi information or a related function uniformly over the orders and priors through a case by case analysis on a subset of  $\mathcal{P}(W)$  or on its neighborhoods.

Lemma 16: Let W be a subset of  $\mathcal{P}(\mathcal{Y})$ .

- (a) For  $\alpha \in (0, 1)$ ,  $C_{\alpha, \mathcal{W}} = \infty$  iff there exists a sequence  $\{p_i\}_{i \in \mathbb{Z}_+} \subset \mathcal{P}(\mathcal{W})$  such that  $\lim_{n \to \infty} \|\mu_{\alpha, p_i}\| = 0$ .
- (b) For  $a \in (1, \infty]$ ,  $C_{a,W} = \infty$  iff there exists a sequence  $\{p_i\}_{i \in \mathbb{Z}_+} \subset \mathcal{P}(W)$  such that  $\lim_{n \to \infty} \|\mu_{a,p_i}\| = \infty$ .
- (c) For  $\alpha \in (1, \infty)$ ,  $C_{\alpha, W} < \infty$  iff  $\mu_{\alpha, p}$  is uniformly continuous in p for the total variation topology.<sup>9</sup>
- (d) For  $\alpha \in [1, \infty]$ ,  $C_{\alpha, \mathcal{W}} < \infty$  iff  $I_{\alpha}(p; \mathcal{W})$  is continuous in p on  $\mathcal{P}(\mathcal{W})$  for the total variation topology.
- (e) For  $\eta \in \Re_{\geq 0}$ , if  $C_{\eta,\mathcal{W}} < \infty$ , then  $\{I_{\alpha}(p;\mathcal{W})\}_{\alpha \in [0,\eta]}$  is uniformly equicontinuous, <sup>10</sup> in p on  $\mathcal{P}(\mathcal{W})$ .

<sup>9</sup>For  $\alpha \in (0, 1]$ ,  $\mu_{\alpha,p}$  is uniformly continuous in *p*, even when  $C_{\alpha,\mathcal{W}} = \infty$ , because  $\mu_{\alpha,p}$  is Lipschitz continuous on  $\mathcal{P}(\mathcal{P}(\mathcal{Y}))$  by Lemma 4-(d).

<sup>10</sup>For  $a \in (0, 1)$ , Lemma 6-(a) has established the continuity of  $I_a(p; \mathcal{W})$  in p without assuming  $C_{a,\mathcal{W}}$  to be finite; but the continuity is not uniform.

- (f) For  $\eta \in \mathfrak{R}_+$ , if  $C_{\eta, W} < \infty$ , then  $\{I_{\alpha}(p; W)\}_{p \in \mathcal{P}(W)}$  is uniformly equicontinuous in  $\alpha$  on every compact subset of  $(0, \eta)$ .<sup>11</sup>
- (g) If  $|W| < \infty$ , then  $C_{\alpha,W}$  is nondecreasing and continuous in  $\alpha$  on  $[0, \infty]$ .

Proof of Lemma 16 is presented in [48, Appendix C]. For W's with infinite  $C_{\alpha,W}$ , the proof of part (d) establishes the discontinuity at every p in  $\mathcal{P}(W)$ . For order one the discontinuity of  $I_1(p;W)$  was observed by Ho and Yeung [35, Th. 3] for a different topology for some W. For the same topology they established the continuity of  $I_1(p;W)$  whenever  $\mathcal{Y}$ is finite [35, Corollary 8]. They, however, did not characterize the conditions for the continuity of  $I_1(p;W)$  in their framework.

## IV. THE RÉNYI CENTER

The primary focus of this section is Theorem 1, given in the following, and its applications. In §IV-A we prove Theorem 1 and discuss alternative proofs based on Sion's minimax theorem. In §IV-B we first prove a lower bound on  $S_{a,W}(q)$ , i.e. the van Erven-Harremoës bound, then we use this bound to establish the continuity of the Rényi center as a function of the order. §IV-C is composed of various applications of Theorem 1 and the van Erven-Harremoës bound.

Theorem 1: For any  $\alpha \in (0, \infty]$  and  $\mathcal{W} \subset \mathcal{P}(\mathcal{Y})$ 

$$C_{\alpha,\mathcal{W}} = \sup_{p \in \mathcal{P}(\mathcal{W})} \inf_{q \in \mathcal{P}(\mathcal{Y})} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q)$$
(31)

$$= \inf_{q \in \mathcal{P}(\mathcal{Y})} \sup_{p \in \mathcal{P}(\mathcal{W})} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q) \quad (32)$$

$$= \inf_{q \in \mathcal{P}(\mathcal{Y})} \sup_{w \in \mathcal{W}} D_{\alpha}(w \parallel q).$$
(33)

If  $C_{\alpha,W} < \infty$ , then there exists a unique  $q_{\alpha,W}$  in  $\mathcal{P}(\mathcal{Y})$ , called the order  $\alpha$  Rényi center, such that

$$C_{\alpha,\mathcal{W}} = \sup_{p \in \mathcal{P}(\mathcal{W})} D_{\alpha} \left( p \circledast \mathcal{W} \| p \otimes q_{\alpha,\mathcal{W}} \right)$$
(34)

$$= \sup_{w \in \mathcal{W}} D_{\alpha} \left( w \| q_{\alpha, \mathcal{W}} \right).$$
(35)

Furthermore, for every sequence of priors  $\{p_i\}_{i \in \mathbb{Z}_+}$  satisfying  $\lim_{i \to \infty} I_{\alpha}(p_i; W) = C_{\alpha, W}$ , the corresponding sequence of order  $\alpha$  Rényi means  $\{q_{\alpha, p_i}\}_{i \in \mathbb{Z}_+}$  is a Cauchy sequence for the total variation metric on  $\mathcal{P}(\mathcal{Y})$  and  $q_{\alpha, W}$  is the unique limit point of that Cauchy sequence.

Theorem 1 is stated for p's that are probability mass functions on W. However, the interpretation of the capacity as the radius implicit in (33) and (35) can be used to extend Theorem 1 to the case when p's are appropriately defined probability measures, see Theorem 3 in Appendix B.

For finite orders, neither the Rényi capacity nor the Rényi center has a closed form expression; this, however, is not the case for order infinity. The following expressions can be confirmed using the observation described in (39) by the interested reader.

$$C_{\infty,\mathcal{W}} = \ln \left\| \bigvee_{w \in \mathcal{W}} w \right\|,\tag{36}$$

$$q_{\infty,\mathcal{W}} = \left(\bigvee_{w\in\mathcal{W}} w\right) e^{-C_{\infty,\mathcal{W}}}.$$
(37)

<sup>&</sup>lt;sup>11</sup>In order to prove the uniform equicontinuity on compact subsets of  $(0, \eta)$ , we prove the following stronger statement: On every compact subset of  $(0, \eta)$ ,  $\{I_{\alpha}(p; \mathcal{W})\}_{p \in \mathcal{P}(\mathcal{W})}$  is a family of Lipschitz continuous functions of  $\alpha$  with a common Lipschitz constant, see [48, eq. (A.24)].

Before presenting the proof and applications of Theorem 1, let us make a brief digression and discuss what is achieved by Theorem 1 itself.

The expression in (33) is nothing but the definition of the order  $\alpha$  Rényi radius  $S_{\alpha,W}$ . Hence, Theorem 1 establishes the equality of the order  $\alpha$  Rényi capacity and the order  $\alpha$  Rényi radius. We prefer to express the equality of  $C_{\alpha,W}$  and  $S_{\alpha,W}$  as a minimax equality because unlike the equality of  $C_{\alpha,W}$  and in the constrained variant of the problem, see Theorem 2 of Appendix A.

Theorem 1 strengthens this minimax equality by asserting the existence of a unique Rényi center that is achieving the infimum in (32). Recall that we have already established, in Lemma 14, the existence of a unique Rényi mean  $q_{\alpha,p}$  achieving the infimum in (31) for any pin  $\mathcal{P}(W)$ . The suprema in (31) and (32), however, cannot be replaced by maxima in general. [48, Example 4] provides a  $\mathcal{W}$  for which  $\inf_{q \in \mathcal{P}(\mathcal{Y})} D_{\alpha}(p \circledast \mathcal{W} || p \otimes q) < C_{\alpha,\mathcal{W}}$  and  $D_{\alpha}(p \circledast \mathcal{W} || p \otimes q_{\alpha,\mathcal{W}}) < C_{\alpha,\mathcal{W}}$  for all p in  $\mathcal{P}(W)$ . Evidently, this subtlety exists only for infinite  $\mathcal{W}$ 's; for finite  $\mathcal{W}$ 's the compactness of  $\mathcal{P}(\mathcal{W})$  and the extreme value theorem guarantees the existence of a p achieving the supremum.

The last assertion of Theorem 1, relating the problem of determining the Rényi capacity to the problem of determining the Rényi center, is important because of its potential in simplifying the problem of determining the Rényi center — defined as the unique  $q_{\alpha,W}$  satisfying (35).

In addition, Theorem 1 provides a necessary and sufficient condition for a prior p to satisfy  $I_{\alpha}(p; W) = C_{\alpha, W}$ . That is important because we do not have a closed form expression for the order  $\alpha$  Rényi capacity, yet occasionally the symmetries of the elements of W or numerical calculations suggest a prior p that might satisfy  $I_{\alpha}(p; W) = C_{\alpha, W}$ .

$$I_{\alpha}(p; \mathcal{W}) = C_{\alpha, \mathcal{W}} \quad \text{iff } S_{\alpha, \mathcal{W}}(q_{\alpha, p}) \le I_{\alpha}(p; \mathcal{W}).$$
(38)

In order to see why (38) holds, note that if  $I_{\alpha}(p; W) = C_{\alpha, W}$ then considering the sequence  $\{p_i\}_{i \in \mathbb{Z}_+}$  where  $p_i = p$  we can conclude that  $q_{\alpha,p} = q_{\alpha,W}$ . Then  $S_{\alpha,W}(q_{\alpha,p}) \leq I_{\alpha}(p; W)$  by (35). On the other hand, if  $S_{\alpha,W}(q_{\alpha,p}) \leq I_{\alpha}(p; W)$  for some p in  $\mathcal{P}(W)$ , then  $I_{\alpha}(p; W) = C_{\alpha,W}$  by (33) because  $I_{\alpha}(p; W) \leq C_{\alpha,W}$ and  $S_{\alpha,W} \leq S_{\alpha,W}(q_{\alpha,p})$  by the definitions of Rényi capacity and center.

Following a similar reasoning one can show that  $\{p_i\}_{i \in \mathbb{Z}_+}$  is optimal iff  $S_{\alpha, \mathcal{W}}(\lim_{i \to \infty} q_{\alpha, p_i}) \leq \lim_{i \to \infty} I_{\alpha}(p_i; \mathcal{W})$ . We chose the following less explicit characterization over the aforementioned one in order to avoid ensuring the convergence of probability measures formally.

$$\lim_{\iota \to \infty} I_{\alpha}(\varphi_{\iota}; \mathcal{W}) = C_{\alpha, \mathcal{W}} \text{ iff } \exists q \colon S_{\alpha, \mathcal{W}}(q) \le \lim_{\iota \to \infty} I_{\alpha}(\varphi_{\iota}; \mathcal{W})$$
(39)

where  $q \in \mathcal{P}(\mathcal{Y})$  is implicit for the latter statement. The Rényi capacity is determined in [48, Examples 1, 3, and 4] using (38) and in [48, Examples 2 and 9, Appendix G] using (39).

(34) of Theorem 1 and (22) imply that

$$D_{\alpha}(q_{\alpha,p} \| q_{\alpha,\mathcal{W}}) \leq C_{\alpha,\mathcal{W}} - I_{\alpha}(p;\mathcal{W}) \quad \forall p \in \mathcal{P}(\mathcal{W}).$$
(40)

Consequently,  $D_{\alpha}(q_{\alpha,p} || q_{\alpha,W})$  is close to zero whenever  $I_{\alpha}(p;W)$  is close to  $C_{\alpha,W}$ .

#### A. Minimax Theorems and the Relative Compactness

We start by proving Theorem 1 for finite W case. In this case Theorem 1 can be strengthened slightly because the existence of an optimal prior is guaranteed. The optimal prior, however, is not necessarily unique, see [48, Example 3]; even then, all such *p*'s have exactly the same Rényi mean. For finite  $\mathcal{Y}$ case, Lemma 17 is well-known, though in a slightly different form, see [22, Th. 4.5.1], [14, p. 128] for  $\alpha = 1$  case and [22, Th. 5.6.5], [14, p. 172] for  $\alpha \in (0, 1)$  case. [11, Thm. 3.2] of Csiszár implies Lemma 17 for  $\alpha$ 's in  $\Re_+$ .

Lemma 17: For any  $\alpha$  in  $[0, \infty]$  and finite subset W of  $\mathcal{P}(\mathcal{Y})$ ,  $\exists \tilde{p} \in \mathcal{P}(W)$  such that  $I_{\alpha}(\tilde{p}; W) = C_{\alpha, W}$ . If  $\alpha$  is in  $(0, \infty]$ , then  $\exists ! q_{\alpha, W} \in \mathcal{P}(\mathcal{Y})$  such that,

$$D_{\alpha}(q_{\alpha,p} \| q_{\alpha,\mathcal{W}}) \le C_{\alpha,\mathcal{W}} - I_{\alpha}(p;\mathcal{W}) \quad \forall p \in \mathcal{P}(\mathcal{W}).$$
(41)

Hence,  $q_{\alpha,\tilde{p}} = q_{\alpha,W}$  for all  $\tilde{p}$  such that  $I_{\alpha}(\tilde{p};W) = C_{\alpha,W}$ . Proof:

- (i)  $\exists \widetilde{p} \in \mathcal{P}(W)$  such that  $I_{\alpha}(\widetilde{p}; W) = C_{\alpha, W}$ : Since  $|\operatorname{supp}(p)| \leq |W|$  for all  $p \in \mathcal{P}(W)$ ,  $C_{\alpha, W} \leq \ln |W|$  by Lemma 5. Then  $I_{\alpha}(p; W)$  is continuous on  $\mathcal{P}(W)$  by Lemmas 6-(a) and 16-(d). Then there exists a  $\widetilde{p}$  achieving the supremum by the extreme value theorem, [46, Th. 27.4] because  $\mathcal{P}(W)$  is compact for finite W.
- (ii) If  $I_{\alpha}\widetilde{p}; W$  =  $C_{\alpha,W}$  for an  $\alpha \in (0, \infty]$ , then  $D_{\alpha}(q_{\alpha,p} || q_{\alpha,\widetilde{p}}) \leq C_{\alpha,W} - I_{\alpha}(p; W)$  for all  $p \in \mathcal{P}(W)$ : Let  $\widetilde{p} \in \mathcal{P}(W)$  be such that  $I_{\alpha}\widetilde{p}; W$  =  $C_{\alpha,W}$ , p be any member of  $\mathcal{P}(W)$  and  $p_{\iota}$  be  $p_{\iota} = \frac{\iota-1}{\iota}\widetilde{p} + \frac{1}{\iota}p$  for  $\iota \in \mathbb{Z}_{+}$ . For  $\alpha = \infty$  using Lemma 14 we get

$$egin{aligned} &I_{\infty}(\!\!\!p_{t}; \mathcal{W}\!\!\!) = \left[I_{\infty}(\!\!\!\!\widetilde{p}; \mathcal{W}\!\!\!) + D_{\infty}(q_{\infty, \widetilde{p}} \| q_{\infty, p_{t}})
ight] \ & imes \left[I_{\infty}(\!\!\!p; \mathcal{W}\!\!) + D_{\infty}(q_{\infty, p} \| q_{\infty, p_{t}})
ight]. \end{aligned}$$

Then  $D_{\infty}(q_{\infty,\tilde{p}} || q_{\infty,p_i}) = 0$  because  $I_{\infty}(p_i; \mathcal{W}) \leq C_{\infty,\mathcal{W}}$ and  $I_{\infty}(\tilde{p}; \mathcal{W}) = C_{\infty,\mathcal{W}}$ . Consequently  $q_{\infty,\tilde{p}} = q_{\infty,p_i}$  and  $I_{\infty}(p_i; \mathcal{W}) = C_{\infty,\mathcal{W}}$ . Thus

$$I_{\infty}(p; \mathcal{W}) + D_{\infty}(q_{\infty, p} \| q_{\infty, \tilde{p}}) \le C_{\infty, \mathcal{W}}.$$
 (42)

For  $\alpha = 1$  and  $\alpha \in \mathfrak{R}_+ \setminus \{1\}$  we have

$$I_{1}(\varphi_{l}; \mathcal{W}) = \frac{l-1}{l} \left[ I_{1}(\widetilde{\varphi}; \mathcal{W}) + D_{1}(q_{1,\widetilde{\rho}} || q_{1,p_{l}}) \right] \\ + \frac{1}{l} \left[ I_{1}(\varphi; \mathcal{W}) + D_{1}(q_{1,p} || q_{1,p_{l}}) \right], \\ I_{\alpha}(\varphi_{l}; \mathcal{W}) = \frac{1}{a-1} \ln \left[ \frac{l-1}{l} e^{(\alpha-1)(I_{\alpha}(\widetilde{\rho}; \mathcal{W}) + D_{\alpha}(q_{\alpha,\widetilde{\rho}} || q_{\alpha,p_{l}})))} \\ + \frac{1}{l} e^{(\alpha-1)(I_{\alpha}(p; \mathcal{W}) + D_{\alpha}(q_{\alpha,\rho} || q_{\alpha,p_{l}})))} \right].$$

Then using  $I_{\alpha}(p_{i}; \mathcal{W}) \leq C_{\alpha, \mathcal{W}}, I_{\alpha}\widetilde{p}; \mathcal{W} = C_{\alpha, \mathcal{W}}$ , and  $D_{\alpha}(q_{\alpha, \widetilde{p}} || q_{\alpha, p_{i}}) \geq 0$  we get the following identity

$$I_{\alpha}(p; \mathcal{W}) + D_{\alpha}(q_{\alpha, p} \| q_{\alpha, p_{l}}) \leq C_{\alpha, \mathcal{W}}.$$

Similarly, using  $I_{\alpha}(p_i; \mathcal{W}) \leq C_{\alpha, \mathcal{W}}, I_{\alpha}(\tilde{p}; \mathcal{W}) = C_{\alpha, \mathcal{W}}, I_{\alpha}(p; \mathcal{W}) \geq 0$ , and  $D_{\alpha}(q_{\alpha, p} || q_{\alpha, p_i}) \geq 0$  we get

$$D_{\alpha}\left(q_{\alpha,\widetilde{p}} \| q_{\alpha,p_{l}}\right) \leq \begin{cases} \frac{1}{\alpha-1} \ln \frac{l-e^{(1-\alpha)C_{\alpha,W}}}{l-1} & \alpha \in \mathfrak{R}_{+} \setminus \{1\} \\ \frac{C_{\alpha,W}}{l-1} & \alpha = 1. \end{cases}$$

Then  $q_{\alpha,p_l} \rightarrow q_{\alpha,\tilde{p}}$  in the total variation topology by Lemma 10. Thus

$$D_{\alpha}(q_{\alpha,p} \| q_{\alpha,\widetilde{p}}) \leq \liminf_{\iota \to \infty} D_{\alpha}(q_{\alpha,p} \| q_{\alpha,p_{\iota}})$$

by Lemma 13. Then

$$I_{\alpha}(p; \mathcal{W}) + D_{\alpha}(q_{\alpha, p} \| q_{\alpha, \tilde{p}}) \le C_{\alpha, \mathcal{W}} \quad \forall \alpha \in \mathfrak{R}_{+}.$$
(43)

(iii) If  $\alpha \in (0, \infty]$ , then  $\exists ! q_{\alpha, W} \in \mathcal{P}(\mathcal{Y})$  satisfying (41) such that  $q_{\alpha,p} = q_{\alpha,\mathcal{W}}$  for all p with  $I_{\alpha}(p;\mathcal{W}) = C_{\alpha,\mathcal{W}}$ : (42), (43) and Lemma 10 implies that

$$I_{\alpha}(p; \mathcal{W}) + \frac{\alpha \wedge 1}{2} \left\| q_{\alpha, p} - q_{\alpha, \tilde{p}} \right\|^{2} \leq C_{\alpha, \mathcal{V}}$$

Then  $q_{\alpha,\tilde{p}} = q_{\alpha,p}$  for any p satisfying  $I_{\alpha}(p; W) = C_{\alpha,W}$ . 

When  $\mathcal{W}$  is not a finite but an arbitrary subset of  $\mathcal{P}(\mathcal{Y})$ , we cannot invoke the extreme value theorem to establish the existence an optimal prior p satisfying  $I_{\alpha}(p; \mathcal{W}) = C_{\alpha, \mathcal{W}}$ because  $\mathcal{P}(W)$  is not compact. Assuming  $C_{\alpha,W}$  to be finite, Theorem 1 recovers all assertions of Lemma 17, but the existence of an optimal prior, albeit in a weaker form.

*Proof of Theorem 1:* For all  $p \in \mathcal{P}(\mathcal{W})$  and  $q \in \mathcal{P}(\mathcal{Y})$ , (19) implies  $D_{\alpha}(p \otimes W \| p \otimes q) \leq \max_{w \in \text{supp}(p)} D_{\alpha}(w \| q)$ . Then considering p's satisfying p(w) = 1 for a w in W we get

$$\sup_{w \in \mathcal{W}} D_{\alpha}(w \| q) = \sup_{p \in \mathcal{P}(\mathcal{W})} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q) \quad (44)$$

for all  $q \in \mathcal{P}(\mathcal{Y})$ . Note that (32) implies (33) and (34) implies (35) because of (44). Furthermore, (31) is nothing but (28) and expression on the right hand side of (31) is bounded from above by the expression in (32) as a result of max-min inequality. Thus when  $C_{\alpha, W}$  is infinite, (32) holds trivially. When  $C_{\alpha,\mathcal{W}}$  is finite, the converse of max-min inequality, and hence (32), follows from (34). Thus, we can assume  $C_{\alpha, \mathcal{W}}$ to be finite and prove the claims about  $q_{\alpha,W}$  for proving Theorem 1.

(i) If  $C_{\alpha,\mathcal{W}} < \infty$  and  $\lim_{t\to\infty} I_{\alpha}(p_t;\mathcal{W}) = C_{\alpha,\mathcal{W}}$ , then  $\{q_{\alpha,p_i}\}_{i\in\mathbb{Z}_+}$  is a Cauchy sequence in  $\mathcal{P}(\mathcal{Y})$  for the total variation metric: For any sequence  $\{p_i\}_{i\in\mathbb{Z}_+}$  of members of  $\mathcal{P}(\mathcal{W})$  satisfying  $\lim_{l\to\infty} I_{\alpha}(p_l;\mathcal{W}) = C_{\alpha,\mathcal{W}}$ , let  $\{\mathcal{W}_i\}_{i\in\mathbb{Z}_+}$  be a nested sequence of finite subsets of W defined as follows,

$$\mathcal{W}_{l} \triangleq \cup_{j=1}^{l} \operatorname{supp}(p_{j}).$$

Then for any  $\iota \in \mathbb{Z}_+$ , there exists a unique  $q_{\alpha, \mathcal{W}_{\iota}}$ satisfying (41) by Lemma 17. Furthermore,  $\mathcal{P}(\mathcal{W}_1) \subset$  $\mathcal{P}(\mathcal{W}_i)$  for any  $i, j \in \mathbb{Z}_+$  such that  $j \leq i$ . In order to bound  $||q_{\alpha,p_j} - q_{\alpha,p_i}||$  for positive integers j < i, we use the triangle inequality for  $q_{\alpha,p_1}$ ,  $q_{\alpha,p_1}$ , and  $q_{\alpha,\mathcal{W}_i}$ :

$$\|q_{\alpha,p_{j}} - q_{\alpha,p_{i}}\| \leq \|q_{\alpha,p_{j}} - q_{\alpha,\mathcal{W}_{i}}\| + \|q_{\alpha,p_{i}} - q_{\alpha,\mathcal{W}_{i}}\|.$$
(45)

Let us proceed with bounding  $||q_{\alpha,p_1} - q_{\alpha,\mathcal{W}_i}||$ .

$$\begin{aligned} \left\| q_{\alpha,p_{j}} - q_{\alpha,\mathcal{W}_{l}} \right\|^{2} &\leq^{(a)} \frac{2}{\alpha \wedge 1} D_{\alpha} \left( q_{\alpha,p_{j}} \right\| q_{\alpha,\mathcal{W}_{l}} \right) \\ &\leq^{(b)} \frac{2}{\alpha \wedge 1} \left[ C_{\alpha,\mathcal{W}_{l}} - I_{\alpha} \left( p_{j};\mathcal{W}_{l} \right) \right] \\ &\leq^{(c)} \frac{2}{\alpha \wedge 1} \left[ C_{\alpha,\mathcal{W}} - I_{\alpha} \left( p_{j};\mathcal{W} \right) \right]. \end{aligned}$$

where (a) follows from Lemma 10, (b) follows from Lemma 17 because  $\tilde{p}_i \in \mathcal{P}(\mathcal{W}_i)$ , and (c) follows from the identities  $I_{\alpha}(p_1; \mathcal{W}_i) = I_{\alpha}(p_1; \mathcal{W})$  and  $C_{\alpha, \mathcal{W}_i} \leq C_{\alpha, \mathcal{W}}$ . We can obtain a similar bound on  $||q_{\alpha,p_i} - q_{\alpha,W_i}||^2$ . Then  $\{q_{\alpha,p_i}\}$  is a Cauchy sequence by (45).

- - (ii) If  $C_{\alpha,W} < \infty$ , then  $\exists ! q_{\alpha,W}$  in  $\mathcal{P}(\mathcal{Y})$  satisfying  $\lim_{t\to\infty} \|q_{\alpha,\mathcal{W}} - q_{\alpha,p_l}\| = 0 \text{ for all } \{p_l\}_{l\in\mathbb{Z}_+} \text{ satisfy-}$ ing  $\lim_{t\to\infty} I_{\alpha}(p_t; \mathcal{W}) = C_{\alpha, \mathcal{W}}$ : Note that  $\mathcal{M}(\mathcal{Y})$  is a complete metric space for the total variation metric, i.e. every Cauchy sequence has a unique limit point in  $\mathcal{M}(\mathcal{Y})$ , because  $\mathcal{M}(\mathcal{Y})$  is a Banach space for the total variation topology [6, Th. 4.6.1]. Then  $\{q_{\alpha,p_l}\}_{l\in\mathbb{Z}_+}$  has a unique limit point  $q_{\alpha, W}$  in  $\mathcal{M}(\mathcal{Y})$ . Since  $\mathcal{P}(\mathcal{Y})$  is a closed set for the total variation topology and  $q_{\alpha,p_l} \in$  $\mathcal{P}(\mathcal{Y})$  for all  $\iota \in \mathbb{Z}_+$ , the limit point  $q_{a,\mathcal{W}}$  is in  $\mathcal{P}(\mathcal{Y})$ by [46, Th. 2.1.3].

We have established the existence of a unique limit point for any  $\{p_i\}_{i \in \mathbb{Z}_+}$  satisfying  $\lim_{i \to \infty} I_{\alpha}(p_i; \mathcal{W}) =$  $C_{\alpha,\mathcal{W}}$ . However, we have not ruled out the possibility of distinct limit points for different sequences satisfying the constraint. Let  $\{p_i\}_{i \in \mathbb{Z}_+}$  and  $\{\tilde{p}_i\}_{i \in \mathbb{Z}_+}$  be two sequences satisfying  $\lim_{t\to\infty} I_{\alpha}(p_{i}; W) = \lim_{t\to\infty} I_{\alpha}(\tilde{p}_{i}; W) =$  $C_{\alpha,\mathcal{W}}$ , with limit points  $q_{\alpha,\mathcal{W}}$  and  $\tilde{q}_{\alpha,\mathcal{W}}$ . Let  $\{\hat{p}_i\}_{i\in\mathbb{Z}_+}$ be a sequence whose elements for the odd indices are the elements of  $\{p_i\}_{i\in\mathbb{Z}_+}$  and whose elements for the even indices are the elements of  $\{\tilde{p}_i\}_{i\in\mathbb{Z}_+}$ . Then  $\lim_{l\to\infty} I_{\alpha}(\hat{p}_{l};\mathcal{W}) = C_{\alpha,\mathcal{W}}$ ; consequently the sequence  $\{q_{\alpha,\hat{p}_l}\}_{l\in\mathbb{Z}_+}$  is Cauchy. Thus  $\{q_{\alpha,\hat{p}_l}\}_{l\in\mathbb{Z}_+}$  and all of its subsequences has the same unique limit point  $\hat{q}_{\alpha,\mathcal{W}}$ . Then  $q_{\alpha,\mathcal{W}} = \hat{q}_{\alpha,\mathcal{W}} = \tilde{q}_{\alpha,\mathcal{W}}$ .

(iii)  $q_{\alpha,W}$  satisfies the equality given in (34): For any p in  $\mathcal{P}(\mathcal{W})$ , let us consider a sequence  $\{p_i\}_{i\in\mathbb{Z}_+}$  satisfying both  $p_1 = p$  and  $\lim_{t \to \infty} I_{\alpha}(p_t; W) = C_{\alpha, W}$ . Then  $p \in$  $\mathcal{P}(\mathcal{W}_i)$  for all  $i \in \mathbb{Z}_+$ . Then using the inequality given in (41) of Lemma 17 together with (22) we get

$$D_{\alpha}\left(p \circledast \mathcal{W} \| p \otimes q_{\alpha, \mathcal{W}_{l}}\right) \le C_{\alpha, \mathcal{W}_{l}} \qquad \forall l. \qquad (46)$$

Since  $W_i$  is a finite set,  $\exists \tilde{p}_i \in \mathcal{P}(W_i)$  satisfying  $I_{\alpha}(\widetilde{p}_{l}; \mathcal{W}_{l}) = C_{\alpha, \mathcal{W}_{l}}$  and  $q_{\alpha, \widetilde{p}_{l}} = q_{\alpha, \mathcal{W}_{l}}$  by Lemma 17. Then  $I_{\alpha}(\widetilde{p}_{i}; \mathcal{W}_{i}) \geq I_{\alpha}(p_{i}; \mathcal{W}_{i})$  because  $p_{i} \in \mathcal{P}(\mathcal{W}_{i})$  by construction. Consequently  $\lim_{i\to\infty} I_{\alpha}(\widetilde{p}_i; \mathcal{W}) = C_{\alpha, \mathcal{W}}$ . We have already established that for such a sequence  $q_{\alpha,\tilde{p}_i} \rightarrow q_{\alpha,\mathcal{W}}$  in the total variation topology, and hence in the topology of setwise convergence. Then the lower semicontinuity of the Rényi divergence, i.e. Lemma 13, the identity  $C_{\alpha, \mathcal{W}_i} \leq C_{\alpha, \mathcal{W}}$ , and (46) imply

$$D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q_{\alpha, \mathcal{W}}) \leq C_{\alpha, \mathcal{W}}.$$

Thus using (24) we get

$$I_{\alpha}(p; \mathcal{W}) \leq D_{\alpha}(p \circledast \mathcal{W} || p \otimes q_{\alpha, \mathcal{W}}) \leq C_{\alpha, \mathcal{W}} \quad \forall p \in \mathcal{P}(\mathcal{W}).$$
  
Then (34) follows the definition of  $C_{\alpha, \mathcal{W}}$ .

Theorem 1 is not just a minimax theorem, the assertions about the Rényi center are crucial. But those assertions can be derived separately, if need be. Leaving them aside, we discuss in the rest of this subsection when (32) can be proved using Sion's minimax theorem [38], [69].

Note that  $\mathcal{P}(\mathcal{W})$  is compact iff  $\mathcal{W}$  is a finite set and  $\mathcal{P}(\mathcal{Y})$ is compact iff  $\mathcal{Y}$  is a finite set. Consequently, when either  $\mathcal{W}$  or  $\mathcal{Y}$  is finite (32) is an immediate consequence of Sion's minimax theorem [38], [69]. When  $\mathcal{W}$  and  $\mathcal{Y}$  are both infinite sets, however, neither  $\mathcal{P}(\mathcal{W})$  nor  $\mathcal{P}(\mathcal{Y})$  is compact —for the total variation topology— and we cannot directly apply Sion's minimax theorem. Yet, it is possible to recover partial results using the concept of relative compactness. Recall that a set of points in a topological space is called relatively compact if it has a compact closure.

First note that as a result of Lemma 14

$$I_{\alpha}(p; \mathcal{W}) = \inf_{q \in cl \mathcal{Q}_{\alpha, \mathcal{W}}} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q)$$
(47)

for all *p*'s in  $\mathcal{P}(\mathcal{W})$  and  $\alpha$ 's in  $\mathfrak{R}_+$  where  $\mathfrak{Q}_{\alpha,\mathcal{W}}$  is the convex hull of the set of all order  $\alpha$  Rényi means:

$$\mathcal{Q}_{\alpha,\mathcal{W}} \triangleq \operatorname{ch}\{q_{\alpha,p} : p \in \mathcal{P}(\mathcal{W})\}.$$

If  $Q_{\alpha,W}$  is relatively compact in the topology of setwise convergence, Sion's minimax theorem imply that

$$\sup_{p \in \mathcal{P}(\mathcal{W})} \inf_{q \in clQ_{a,\mathcal{W}}} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q)$$
  
= 
$$\inf_{q \in clQ_{a,\mathcal{W}}} \sup_{p \in \mathcal{P}(\mathcal{W})} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q). \quad (48)$$

We can replace  $clQ_{\alpha,W}$  by  $\mathcal{P}(\mathcal{Y})$  in the expression on the left hand side without changing its value as a result of (47). However, that operation can decrease the value of the right hand side because  $clQ_{\alpha,W} \subset \mathcal{P}(\mathcal{Y})$ . Thus we get,

$$\sup_{p \in \mathcal{P}(\mathcal{W})} \inf_{q \in \mathcal{P}(\mathcal{Y})} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q) \\ \geq \inf_{q \in \mathcal{P}(\mathcal{Y})} \sup_{p \in \mathcal{P}(\mathcal{W})} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q) .$$

The reverse inequality is the max-min inequality, which is always valid. Thus (32) holds.

A set of finite measures  $\mathcal{W}$  is relatively compact in the topology of setwise convergence iff there exists a  $v \in \mathcal{P}(\mathcal{Y})$  such that  $\mathcal{W} \prec^{uni} v$  by a version of the Dunford-Pettis theorem [6, Th. 4.7.25]. Using de la Vallée Poussin's characterization of the uniform integrability [6, Th. 4.5.9] and monotonicity of the order  $\alpha$  mean measure  $\mu_{\alpha,p}$  in the order, i.e. Lemma 3-(b), we can obtain sufficient conditions for the relative compactness of  $\Omega_{\alpha,\mathcal{W}}$  in the topology of setwise convergence for any  $\alpha \in \Re_+$ . As a result we get the following partial result:

Lemma 18: Let W be subset of  $\mathcal{P}(\mathcal{Y})$ .

- (i) If  $\exists v \in \mathcal{P}(\mathcal{Y})$  such that  $\mathcal{W} \prec^{uni} v$  and  $S_{\eta, \mathcal{W}} < \infty$  for an  $\eta \in (0, 1)$ , then (32) holds  $\forall \alpha \in (0, 1)$ .
- (ii) If  $S_{\eta,\mathcal{W}} < \infty$  for an  $\eta \in [1, \infty]$ , then (32) holds  $\forall \alpha \in (0, \eta]$ .

#### B. The Rényi Center as a Function of the Order

 $S_{\alpha,W}$  is defined as the greatest lower bound of  $S_{\alpha,W}(q)$ . Then Theorem 1 implies, by establishing  $C_{\alpha,W} = S_{\alpha,W}$ , that

$$S_{\alpha,\mathcal{W}}(q) \ge C_{\alpha,\mathcal{W}} \qquad \forall q \in \mathcal{P}(\mathcal{Y}).$$

Van Erven and Harremoës have conjectured that a better lower bound on  $S_{\alpha,W}(q)$  should hold, [18, Conjecture 1]. Van Erven and Harremoës proved their claim for  $\alpha = \infty$  case assuming that  $\mathcal{Y}$  is countable, [18, Thm. 37]. Lemma 19 establishes the van Erven-Harremoës bound for any positive order  $\alpha$  and  $\mathcal{W}$  satisfying  $C_{\alpha,\mathcal{W}} < \infty$ , using Theorem 1. A constrained generalization, i.e. Lemma 25, can be found in Appendix A.  $\square$ 

Lemma 19: For any  $\alpha \in (0, \infty]$ ,  $\mathcal{W} \subset \mathcal{P}(\mathcal{Y})$  satisfying  $C_{\alpha, \mathcal{W}} < \infty$ , and  $q \in \mathcal{P}(\mathcal{Y})$ ,

$$\sup_{w \in \mathcal{W}} D_{\alpha}(w \| q) \ge C_{\alpha, \mathcal{W}} + D_{\alpha}(q_{\alpha, \mathcal{W}} \| q).$$
(49)

Lemma 19 quantifies how loose  $S_{\alpha, W}(q)$  —defined in (1) is as an upper bound to  $C_{\alpha, W}$ , as surmised by van Erven and Harremoës in [18].

Proof of Lemma 19: As a result of (22) and (23) we have,

$$\sup_{\tilde{p}\in\mathcal{P}(\mathcal{W})} D_{\alpha}(\tilde{p}\circledast\mathcal{W} \| \tilde{p}\otimes q) \ge D_{\alpha}(p\circledast\mathcal{W} \| p\otimes q)$$
$$= I_{\alpha}(p;\mathcal{W}) + D_{\alpha}(q_{\alpha,p} \| q) \quad (50)$$

for all  $p \in \mathcal{P}(\mathcal{W})$ . Let  $\{p_i\}_{i \in \mathbb{Z}_+}$  be a sequence of elements of  $\mathcal{P}(\mathcal{W})$  such that  $\lim_{i\to\infty} I_\alpha(p_i;\mathcal{W}) = C_{\alpha,\mathcal{W}}$ . Then the sequence  $\{q_{\alpha,p_i}\}_{i\in\mathbb{Z}_+}$  is a Cauchy sequence with the unique limit point  $q_{\alpha,\mathcal{W}}$  by Theorem 1. Since  $\{q_{\alpha,p_i}\} \to q_{\alpha,\mathcal{W}}$  in total variation topology, same convergence holds in the topology of setwise convergence because every open neighborhood in the latter includes an open neighborhood in the former by the definitions of these topologies. On the other hand, the order  $\alpha$  Rényi divergence is lower semicontinuous for the topology of setwise convergence by Lemma 13. Thus we have

$$\liminf_{\iota\to\infty} \left[ I_{\alpha}(p_{\iota}; \mathcal{W}) + D_{\alpha}(q_{\alpha, p_{\iota}} \| q) \right] \geq C_{\alpha, \mathcal{W}} + D_{\alpha}(q_{\alpha, \mathcal{W}} \| q).$$

Then (49) follows from (44) and (50).

The van Erven-Harremoës bound allows us to use the continuity of  $C_{\alpha,W}$  in  $\alpha$  and Pinsker's inequality to establish the continuity of  $q_{\alpha,W}$  in  $\alpha$  for the total variation topology.

Lemma 20: For any  $W \subset \mathcal{P}(\mathcal{Y})$  and  $\eta \in (0, \infty]$  such that  $C_{\eta, \mathcal{W}} < \infty$ ,

$$C_{\phi,\mathcal{W}} - C_{\alpha,\mathcal{W}} \ge D_{\alpha} \left( q_{\alpha,\mathcal{W}} \| q_{\phi,\mathcal{W}} \right) \tag{51}$$

for all  $\alpha$  and  $\phi$  satisfying  $0 < \alpha < \phi \leq \eta$ . Furthermore,  $q_{\alpha,W}$  is a continuous function of  $\alpha$  on  $(0, \eta]$  for the total variation topology on  $\mathcal{P}(\mathcal{Y})$ .

The continuity of the Rényi center as a function of the order is important because it allows us to the interpret the Rényi centers as a transition probability from the interval on which the Rényi capacity is finite to  $(\mathcal{Y}, \mathcal{Y})$  and apply Augustin's method, see [51, §III-A] for a more detailed discussion.

*Proof of Lemma 20:* For  $q = q_{\phi, W}$ , Lemma 19 implies

$$\sup_{w \in \mathcal{W}} D_{\alpha} \left( w \| q_{\phi, \mathcal{W}} \right) \ge C_{\alpha, \mathcal{W}} + D_{\alpha} \left( q_{\alpha, \mathcal{W}} \| q_{\phi, \mathcal{W}} \right).$$
(52)

Since  $D_{\alpha}(w \parallel q_{\phi, W})$  is nondecreasing in  $\alpha$  by Lemma 7,

$$D_{\phi}(w \| q_{\phi, \mathcal{W}}) \ge D_{\alpha}(w \| q_{\phi, \mathcal{W}}) \quad \forall w \in \mathcal{W}, \ \phi \in [\alpha, \eta].$$
(53)

On the other hand by (35) of Theorem 1 we have

$$C_{\phi,\mathcal{W}} = \sup_{w \in \mathcal{W}} D_{\phi} (w \| q_{\phi,\mathcal{W}}) \quad \forall \phi \in (0, \eta].$$
(54)

(51) follows from (52), (53), and (54).

Using Lemma 10 and (51) we get

$$\sqrt{\frac{2}{\phi \wedge 1}} (C_{\phi, \mathcal{W}} - C_{a, \mathcal{W}}) \ge \left\| q_{\phi, \mathcal{W}} - q_{a, \mathcal{W}} \right\|.$$
(55)

Then, for the total variation topology on  $\mathcal{P}(\mathcal{Y})$ , the continuity of  $q_{\alpha,\mathcal{W}}$  in  $\alpha$  follows from the continuity  $C_{\alpha,\mathcal{W}}$  in  $\alpha$  on  $(0, \eta]$ , i.e. Lemma 15-(f).

Lemma 19 established the continuity of the Rényi center in the order for the total variation topology. We suspect a much stronger statement is true.

Conjecture 1: For any  $\mathcal{W} \subset \mathcal{P}(\mathcal{Y})$  and  $\eta \in (0, \infty]$ . satisfying  $C_{\eta,\mathcal{W}} < \infty$ ,

$$\mu_{\phi,\mathcal{W}} \le \mu_{\eta,\mathcal{W}} \quad \forall \phi \in (0,\eta] \tag{56}$$

where  $\mu_{\phi,\mathcal{W}} \triangleq e^{\frac{\phi-1}{\phi}C_{\phi,\mathcal{W}}}q_{\phi,\mathcal{W}}$  for all  $\phi \in (0,\eta]$ .

For any W using the continuity of the Rényi center in the order, one can prove that there exists a  $\nu$  in  $\mathcal{P}(\mathcal{Y})$  such that  $\{q_{\alpha,\mathcal{W}}: C_{\alpha,\mathcal{W}} < \infty\} \prec \nu$ . However, the continuity of the Rényi center as a function of the order for the total variation topology does not imply the continuity of corresponding Radon-Nikodym derivative  $\frac{dq_{\alpha,W}}{d\nu}$  as a function of  $\alpha$  for  $\nu$ almost everywhere. If Conjecture 1 is correct, then it will imply the continuity of Radon-Nikodym derivative  $\frac{dq_{\alpha,W}}{dv}$  as a function of  $\alpha$  for  $\nu$ -almost everywhere.

Remark 2: The continuity in the total variation topology does not imply the continuity of the corresponding Radon-Nikodym derivative: Let the output space be the real numbers between -1 and 2, and the Radon-Nikodym derivative of  $q_{\alpha}$ with respect to the Lebesgue measure l be

$$\frac{dq_{\alpha}}{dl} = \mathbb{1}_{\{\sin(\frac{1}{l-\alpha}) \le y \le \sin(\frac{1}{l-\alpha}) + |\alpha-t|\}} + \mathbb{1}_{\{0 \le y \le 1\}} (1 - |\alpha-t|)$$

for a  $t \in (0, 1)$ . Evidently  $\lim_{\eta \to \alpha} \|q_{\alpha} - q_{\eta}\| = 0$  for all  $\alpha$  in (0, 1). But  $\frac{dq_{\alpha}}{dt}$  is not continuous in  $\alpha$  for any  $y \in (0, 1)$  at t.

#### C. The Unions, Cartesian Products, Closures, and More

This subsection is composed of applications of Theorem 1 and Lemma 19. Lemma 21, in the following, bounds from below and from above the Rényi capacity of a union of sets in terms of the Rényi capacities of the sets in the union. Lemma 22 establishes that the Rényi capacity of a Cartesian product is equal to the sum of the Rényi capacities of its components. Lemma 23 shows that for any positive  $\epsilon$  the order  $\alpha$  Rényi capacity of the set of w's in W satisfying  $D_{\alpha}(w \parallel q_{\alpha, \mathcal{W}}) \geq C_{\alpha, \mathcal{W}} - \epsilon$  is equal to  $C_{\alpha, \mathcal{W}}$ . Lemma 24 establishes the invariance of  $C_{\alpha, \mathcal{W}}$  under the closure and convexification operations on W and characterizes the relative compactness of W in terms of its Rényi capacity. Proofs of these lemmas are presented in [48, Appendix C].

Lemma 21: For any  $\alpha \in (0, \infty]$  and  $W \subset \mathcal{P}(\mathcal{Y})$  satisfying  $\mathcal{W} = \bigcup_{i \in \mathcal{T}} \mathcal{W}_i$  for some  $\mathcal{W}_i \subset \mathcal{P}(\mathcal{Y})$  with finite  $C_{a,\mathcal{W}_i}$ 's,

$$\sup_{i\in\mathcal{T}}C_{\alpha,\mathcal{W}_{i}}\leq C_{\alpha,\mathcal{W}}\leq \ln\sum_{i\in\mathcal{T}}e^{C_{\alpha,\mathcal{W}_{i}}}.$$
(57)

Furthermore,

- $C_{\alpha,\mathcal{W}_l} = C_{\alpha,\mathcal{W}} \text{ iff } S_{\alpha,\mathcal{W}}(q_{\alpha,\mathcal{W}_l}) \leq C_{\alpha,\mathcal{W}_l}.$
- If C<sub>a,W<sub>i</sub></sub> = C<sub>a,W</sub>, then q<sub>a,W</sub> = q<sub>a,W<sub>i</sub></sub>.
  C<sub>a,W</sub> = ln ∑<sub>i∈T</sub> e<sup>C<sub>a,W<sub>i</sub></sub> and C<sub>a,W</sub> is finite iff T is finite
  </sup> and  $q_{\alpha, W_{\iota}} \perp q_{\alpha, W_{\iota}}$  for all  $\iota \neq \jmath$  in  $\mathfrak{T}$ .
- If T is finite and  $q_{\alpha,W_i} \perp q_{\alpha,W_j}$  for all  $i \neq j$  in T, then  $q_{\alpha,\mathcal{W}} = (\sum_{j\in\mathcal{T}} e^{C_{\alpha,\mathcal{W}_j}})^{-1} \sum_{i\in\mathcal{T}} e^{C_{\alpha,\mathcal{W}_i}} q_{\alpha,\mathcal{W}_i}.$

One might think that  $q_{\alpha, W_l} \perp q_{\alpha, W_l}$  iff  $W_l \perp W_l$ . This, however, is true only for  $\alpha$ 's in  $[1, \infty]$ . For  $\alpha$ 's in (0, 1),  $\mathcal{W}_{i} \perp \mathcal{W}_{i}$  is a sufficient condition for  $q_{a,\mathcal{W}_{i}} \perp q_{a,\mathcal{W}_{i}}$ , but it is not a necessary condition, see [48, Examples 1 and 2]. Augustin [5] is the first one to point out this subtlety and to present necessary and sufficient conditions for  $C_{\alpha,W}$  =  $\ln \sum_{i \in \mathcal{T}} e^{C_{a,W_i}}$ , to the best of our knowledge. Bounds given in (57) is well known [22, p. 535, Example 5.17]. We use the van Erven-Harremoës bound in order to characterize the necessary and sufficient conditions for  $\sup_{i \in \mathcal{T}} C_{\alpha, \mathcal{W}_i} = C_{\alpha, \mathcal{W}}$ and  $C_{\alpha,\mathcal{W}} = \ln \sum_{i \in \mathcal{T}} e^{C_{\alpha,\mathcal{W}_i}}$ .

Let T be a finite set. For each  $t \in T$ , let  $(\mathcal{Y}_t, \mathcal{Y}_t)$  be a measurable space and  $w_t$  be a probability measure on  $(\mathcal{Y}_t, \mathcal{Y}_t)$ . Then there exists a unique product measure  $\bigotimes_{t \in \mathcal{T}} w_t$  on the measurable space  $(\times_{t \in \mathcal{T}} \mathcal{Y}_t, \otimes_{t \in \mathcal{T}} \mathcal{Y}_t)$  by [17, Th. 8.2.2]. Let  $\mathcal{W}_t$ be a subset of  $\mathcal{P}(\mathcal{Y}_t)$  for each  $t \in \mathcal{T}$ . Then using the existence of a unique product measure we can map the Cartesian product of the sets  $\mathcal{W}_t$  uniquely to a subset of  $\mathcal{P}(\bigotimes_{t \in \mathcal{T}} \mathcal{Y}_t)$ , called the product of  $W_t$ 's. Then the Rényi capacity of the product is equal to the sum of the Rényi capacities of its components and the Rényi center of the product, whenever it exists, is equal to the product of the Rényi centers of its components. Lemma 22 asserts these observations formally.

Lemma 22: For any finite index set T, if  $\mathcal{Y} = \times_{t \in T} \mathcal{Y}_t$ ,  $\mathcal{Y} = \bigotimes_{t \in \mathcal{T}} \mathcal{Y}_t$ , and  $\mathcal{W} = \{w : w = \bigotimes_{t \in \mathcal{T}} w_t : w_t \in \mathcal{W}_t\}$  for some  $\mathcal{W}_t \subset \mathcal{P}(\mathcal{Y}_t)$ , then

$$C_{\alpha,\mathcal{W}} = \sum_{t \in \mathcal{T}} C_{\alpha,\mathcal{W}_t} \quad \forall \alpha \in (0,\infty].$$
(58)

Furthermore, if  $C_{\alpha,\mathcal{W}} < \infty$ , then  $q_{\alpha,\mathcal{W}} = \bigotimes_{t \in \mathcal{T}} q_{\alpha,\mathcal{W}_t}$ .

Quite frequently, the information transmission problems are analyzed on the product W's. Lemma 22 is instrumental when that is the case. The derivation of the sphere packing bound presented in [51, §IV] is a case in point. The additivity of the Rényi capacity for products was first reported by Gallager —in a slightly different form and for finite W and Y case in his seminal paper [20, Th. 5], see also [22, pp. 149-150, eq. (5.6.59)]. Later, Augustin proved [5, Lemma 26.7a], which implies Lemma 22; see [4, Lemma 3.6] for finite W case.

One curious question is whether or not one can give a class of priors for which the lower bound given in (40) is not too loose. Lemma 23 answers this question in the affirmative.

Lemma 23: For any  $\alpha \in (0, \infty]$ ,  $\mathcal{W} \subset \mathcal{P}(\mathcal{Y})$  with finite  $C_{\alpha,\mathcal{W}}$ , and  $\epsilon \geq 0$ , let  $\mathcal{W}_{\alpha,\epsilon}$  be

$$\mathcal{W}_{\alpha,\epsilon} \triangleq \left\{ w \in \mathcal{W} : D_{\alpha} \left( w \| q_{\alpha,\mathcal{W}} \right) \ge C_{\alpha,\mathcal{W}} - \epsilon \right\}.$$
(59)

Then for any  $\epsilon > 0$ , we have  $C_{\alpha, \mathcal{W}_{\alpha, \epsilon}} = C_{\alpha, \mathcal{W}}$  and

$$0 \le C_{\alpha,\mathcal{W}} - I_{\alpha}(p;\mathcal{W}) - D_{\alpha}(q_{\alpha,p} \| q_{\alpha,\mathcal{W}}) \le \epsilon$$
(60)

for all p in  $\mathbb{P}(\mathcal{W}_{\alpha,\epsilon})$ . Furthermore, if  $\mathcal{W}$  is a finite set, then  $C_{\alpha,\mathcal{W}_{\alpha,0}} = C_{\alpha,\mathcal{W}}$  and (60) holds for  $\epsilon = 0$ .

The main conclusion of Lemma 23 is the equality  $C_{\alpha, W_{\alpha, \ell}} =$  $C_{\alpha,\mathcal{W}}$  for positive  $\epsilon$ 's. This is expected for a general  $\mathcal{W}$  and evident, even for  $\epsilon = 0$  case, for a finite W because of the existence of an optimal p in  $\mathcal{P}(W)$  for finite W's. One might be tempted to assume the validity of the assertions for  $\epsilon = 0$ case for arbitrary W's. This, however, is not true; see [48, Example 4] for a  $\mathcal{W}$  for which  $C_{\alpha,\mathcal{W}} > 0$  and  $C_{\alpha,\mathcal{W}_{\alpha,0}} = 0$ . Thus finiteness of W is not a superficial hypothesis for extending the claims to  $\epsilon = 0$  case.

In order to apply certain technical tools, we occasionally need a given set to be closed, convex, or compact. The observations presented in Lemma 24, given in the following, can be helpful in such situations. For example, if we can prove a statement about Rényi capacity assuming W to be convex, then we can assert that statement for non-convex W's using Lemma 24-(a). Furthermore, in certain situations, calculating the Rényi capacity might be easier for the convex hull or the closure of W when compared to W itself, see [48, Example 4]. Lemma 24-(a,b) is helpful in such situations. Note that Lemma 24-(a,b) when considered together with Lemma 21 imply the equality of the Rényi centers of  $\mathcal{W}$ , ch $\mathcal{W}$ , and clW whenever one of them exists.

Lemma 24: Let W be a subset of  $\mathcal{P}(\mathcal{Y})$ .

- (a)  $C_{\alpha, chW} = C_{\alpha, W}$  for all  $\alpha \in (0, \infty]$  where chW is the convex hull of W given by  $chW \triangleq \{\mu_{1,p} : p \in \mathcal{P}(W)\}.$
- (b)  $C_{\alpha,clW} = C_{\alpha,W}$  for all  $\alpha \in (0,\infty]$  where clW is the closure of W in the topology of setwise convergence or a stronger topology on  $\mathcal{P}(\mathcal{Y})$ .
- (c) If  $C_{n,\mathcal{W}} < \infty$  for an  $\eta \ge 1$ , then  $\{\mu_{\alpha,p} : \alpha \in [0, \eta], p \in \mathcal{P}(\mathcal{W})\}$ is uniformly absolutely continuous with respect to  $q_{n,W}$ and relatively compact in both the topology of setwise convergence and the weak topology.
- (d) The following four statements are equivalent:

  - (*i*)  $\lim_{\alpha \uparrow 1} \frac{1-\alpha}{\alpha} C_{\alpha, \mathcal{W}} = 0.$ (*ii*)  $\exists \mu \in \mathcal{P}(\mathcal{Y})$  such that  $\mathcal{W} \prec^{uni} \mu$ .
  - (iii) W has compact closure in the topology of setwise convergence.
  - (iv) W has compact closure in the weak topology.

Each assertion of Lemma 24 is proved using Theorem 1 together with some other observations. The invariance of  $C_{\alpha, \mathcal{W}}$ under the closure and the convexification operations on  $\mathcal{W}$ , presented in Lemma 24-(a,b), follow from the lower semicontinuity and the quasi-convexity of the Rényi divergence in its first argument. Lemma 24-(c) follows from the monotonicity of  $\mu_{\alpha,p}$  in  $\alpha$  and de la Vallée Poussin's characterization of the uniform integrability, i.e. [6, Th. 4.5.9].

Arguably, the most interesting observation of Lemma 24 is the following:  $\lim_{\alpha \uparrow 1} \frac{\alpha - 1}{\alpha} C_{\alpha, \mathcal{W}} = 0$  iff there exists a  $\mu$  in  $\mathcal{P}(\mathcal{Y})$  satisfying  $\mathcal{W} \prec^{uni} \mu$ . This characterization is important because W is relatively compact, i.e. has a compact closure, in the topology of setwise convergence iff there exists a  $\mu$ in  $\mathcal{P}(\mathcal{Y})$  satisfying  $\mathcal{W} \prec^{uni} \mu$  by [6, Th. 4.7.25]. Since the topology of set wise convergence and the weak topology have exactly the same family of sets as their compact sets by [6, Th. 4.7.25], the uniform absolute continuity also characterizes the relative compactness in the weak topology.

*Remark 3:* The weak topology on  $\mathcal{M}(\mathcal{Y})$  is the topology generated by all continuous linear functions from  $\mathcal{M}(\mathcal{Y})$  with the total variation topology to  $\Re$  with its usual topology. Then the weak topology is weaker than the total variation topology, i.e. the initial topology. On the other hand, the topology of setwise convergence on  $\mathcal{M}(\mathcal{Y})$  is the topology generated by the functions  $\{f_{\mathcal{E}} : \mathcal{E} \in \mathcal{Y}\}$  where  $f_{\mathcal{E}}(\mu) = \int_{\mathcal{E}} \mu(dy)$  for  $\mathcal{E}$  in  $\mathcal{Y}$ and  $\mu$  in  $\mathcal{M}(\mathcal{Y})$ . Since  $f_{\mathcal{E}} : \mathcal{M}(\mathcal{Y}) \to \mathfrak{R}$  is a continuous linear function for any  $\mathcal{E} \in \mathcal{Y}$ , the weak topology is stronger than the topology of setwise convergence. Nevertheless, the weak topology and the topology of setwise convergence have exactly the same class of compact sets, [6, Th. 4.7.25].

Our use of the term weak topology is consistent with the convention used in functional analysis, see [6, pp. 281 and 291]. While discussing the convergence of measures, however, the term weak topology is commonly used to describe another topology. If there is a topology on  $\mathcal{Y}$  and  $\mathcal{Y}$  is the resulting Baire  $\sigma$ -algebra [6, p. 12] of the subsets of  $\mathcal{Y}$ , then one can interpret the space of measures as a space of linear functionals on the space of continuous and bounded functions on y. The weak\* topology on the space of measures in this setting is often called the weak topology [6, Definition 8.1.2]. Although it is a very important and useful concept in general, the weak topology in this second sense is not relevant in our discussion because we have not assumed any topological structure on Y.

#### V. DISCUSSION

In this paper, we define and analyze the order  $\alpha$ Rényi capacity  $C_{\alpha,\mathcal{W}}$  and the order  $\alpha$  Rényi radius  $S_{\alpha,\mathcal{W}}$  for an arbitrary set of probability measures W on an arbitrary measurable space. Our most important contributions are proving the van Erven-Harremoës conjecture, i.e. Lemma 19, and two uniform equicontinuity results on the Rényi information, i.e. Lemma 16-(e,f). We also prove a minimax theorem, i.e. Theorem 1, which has been previously reported by Augustin in [5] in a different form and for orders between zero and two. Theorem 1 establishes not only the equality of  $C_{\alpha, W}$  and  $S_{\alpha,\mathcal{W}}$  for any  $\alpha$  and  $\mathcal{W}$  but also the existence of a unique order  $\alpha$  Rényi center whenever  $C_{\alpha, W}$  is finite. Our analysis leads to certain immediate consequences for two generalizations:  $C_{\alpha, \mathcal{W}, \mathcal{A}}$  defined for  $\mathcal{A} \subset \mathcal{P}(\mathcal{W})$  and  $C_{\alpha, \mathcal{W}}$  defined for transition probability W. We introduce those generalizations formally and discuss the implications of our analysis on them in Appendices A and B.

Results of our analysis, also, encourage one to consider certain related problems:

- We do not assume any topological structure on the output space y. Although this is a strength because of the generality of our results, it is also a weakness because of the obliviousness of our analysis towards the interactions between Rényi's information measures and the topological structure of the output space. In almost all of the applications,  $\mathcal{Y}$  is a Borel or Baire  $\sigma$ -algebra of the topological space  $(\mathcal{Y}, \tau)$ ; usually there is an even more specific structure. In most of the applications,  $\mathcal{Y}$  is the Borel  $\sigma$ -algebra of a complete separable metric space  $(\mathcal{Y}, d)$ . Thus one can define metrics other than the total variation metric on W and  $\mathcal{P}(W)$  using the metric d and analyze the behavior of Rényi's information measures on the resulting topologies. Such models have already been considered in the context of the arbitrarily varying channels [12], [70] and the typicality [36], [42], [55].
- It is easy to confirm that continuity of the order  $\alpha$ Rényi capacity as a function of the order  $\alpha$  implies the continuity of the corresponding *f*-capacity  $C_{f_{\alpha},W}$  as a function of  $\alpha$  where  $f_{\alpha}(x) = \frac{x^{\alpha}-1}{\alpha-1}$ . The existence of similar, but more general, continuity results for richer classes of *f*-divergences with appropriate topologies is

expected. What is plausible, but not evident, to us is the existence of a topology on the set of all convex f's that ensures the continuity of the corresponding f-capacities in f for all W on the region that f-capacities are finite. The interaction of topologies on the space of convex functions and corresponding f-capacities seems to be a fertile subject of inquiry.

• We use the definition of the Rényi information proposed by Sibson [68]. In (26) we provide the expression for the alternative definition of the Rényi information proposed by Augustin [5] and Csiszár [13]. We call this quantity the Augustin information. Theorems 1, 2, 3, and many of the other propositions have their analogues for the Augustin information, see [47], [52]. The Augustin capacity and center are of interest to us because they are better suited than the Rényi capacity and center for deriving the sphere packing bound for memoryless channels, see [50], [52].

We have avoided using information theoretic concepts such as code, channel, or rate in our discussion because we believe Rényi 's information measures can and should be defined and understood on their own as measure theoretic concepts first. Rényi 's information measures, however, do have operational meaning in various information transmission problems. We discuss the case of channel coding problem in [51].

#### APPENDIX

A. The Constrained Rényi Capacity

Definition 8: For any  $\alpha \in [0, \infty]$ ,  $\mathcal{W} \subset \mathcal{P}(\mathcal{Y})$ ,  $\mathcal{A} \subset \mathcal{P}(\mathcal{W})$ , the order  $\alpha$  Rényi capacity of  $\mathcal{W}$  for constraint set  $\mathcal{A}$  is

$$C_{\alpha,\mathcal{W},\mathcal{A}} \triangleq \sup_{p \in \mathcal{A}} I_{\alpha}(p;\mathcal{W}).$$
 (A.1)

 $C_{\alpha,\mathcal{W},\mathcal{P}(\mathcal{W})} = C_{\alpha,\mathcal{W}}$  and  $C_{\alpha,\mathcal{W},\{p\}} = I_{\alpha}(p;\mathcal{W})$  for any  $\mathcal{W}$  and  $p \in \mathcal{P}(\mathcal{W})$ .

If we replace  $\mathcal{P}(\mathcal{W})$  with a convex  $\mathcal{A}$ , the proof of Theorem 1 works as is. Thus the minimax theorem continues to hold for  $C_{\alpha,\mathcal{W},\mathcal{A}}$ ; but the alternative expression for  $C_{\alpha,\mathcal{W},\mathcal{A}}$  is no longer (guaranteed to be) equal to the Rényi radius.

Theorem 2: For any  $\alpha \in (0, \infty]$ ,  $W \subset \mathcal{P}(\mathcal{Y})$ , and convex  $\mathcal{A} \subset \mathcal{P}(W)$ ,

$$C_{\alpha,\mathcal{W},\mathcal{A}} = \sup_{p\in\mathcal{A}} \inf_{q\in\mathcal{P}(\mathcal{Y})} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q)$$
(A.2)

$$= \inf_{q \in \mathcal{P}(\mathcal{Y})} \sup_{p \in \mathcal{A}} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q) . \quad (A.3)$$

If  $C_{\alpha,W,\mathcal{A}} < \infty$ , then there exists a unique  $q_{\alpha,W,\mathcal{A}}$  in  $\mathcal{P}(\mathcal{Y})$ , called the order  $\alpha$  Rényi center for constraint set  $\mathcal{A}$ , such that

$$C_{\alpha,\mathcal{W},\mathcal{A}} = \sup_{p \in \mathcal{A}} D_{\alpha} \left( p \circledast \mathcal{W} \| p \otimes q_{\alpha,\mathcal{W},\mathcal{A}} \right).$$
(A.4)

Furthermore, for every sequence of priors  $\{p_i\}_{i \in \mathbb{Z}_+} \subset \mathcal{A}$ satisfying  $\lim_{i\to\infty} I_{\alpha}(p_i; \mathcal{W}) = C_{\alpha,\mathcal{W},\mathcal{A}}$ , the corresponding sequence of order  $\alpha$  Rényi means  $\{q_{\alpha,p_i}\}_{i\in\mathbb{Z}_+}$  is a Cauchy sequence for the total variation metric on  $\mathcal{P}(\mathcal{Y})$  and  $q_{\alpha,\mathcal{W},\mathcal{A}}$ is the unique limit point of that Cauchy sequence.

A similar modification is needed for the van Erven-Harremoës bound, i.e. for Lemma 19, as well.

Lemma 25: For any  $\alpha \in (0, \infty]$ ,  $\mathcal{W} \subset \mathcal{P}(\mathcal{Y})$ , convex  $\mathcal{A} \subset \mathcal{P}(\mathcal{W})$  satisfying  $C_{\alpha,\mathcal{W},\mathcal{A}} < \infty$ , and  $q \in \mathcal{P}(\mathcal{Y})$ 

$$C_{\alpha,\mathcal{W},\mathcal{A}} + D_{\alpha}(q_{\alpha,\mathcal{W},\mathcal{A}} \| q) \leq \sup_{p \in \mathcal{A}} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q).$$

Lemma 20 establishing the continuity of the Rényi centers in the order holds for the constrained Rényi centers. We prove it using Theorem 2 and Lemma 25 instead of Theorem 1 and Lemma 19.

#### B. The Rényi Capacity of Transition Probabilities

We have defined the order  $\alpha$  Rényi information  $I_{\alpha}(p; W)$  for any p.m.f. p on a set of probability measures W. We show in the following —using the concept of transition probability and the expression for  $I_{\alpha}(p; W)$  given in (24)— that for appropriately chosen  $\sigma$ -algebra W, one can extend the definition of  $I_{\alpha}(p; W)$  to p's that are probability measures on (W, W). Furthermore, we show that if W is countably separated, then Theorem 1 holds for this more general case, see Theorem 3.

Definition 9: Let  $(\mathfrak{X}, \mathcal{X})$  and  $(\mathcal{Y}, \mathcal{Y})$  be measurable spaces. Then a function  $W : \mathfrak{X} \times \mathcal{Y} \to [0, 1]$  is called a transition probability (a stochastic kernel / a Markov kernel) from  $(\mathfrak{X}, \mathcal{X})$ to  $(\mathcal{Y}, \mathcal{Y})$  if it satisfies the following two conditions:

- (i) For all x ∈ X, the function W(·|x) : Y → [0, 1] is a probability measure on (Y, Y).
- (ii) For all  $\mathcal{E} \in \mathcal{Y}$ , the function  $W(\mathcal{E}|\cdot) : \mathcal{X} \to [0, 1]$  is a  $\mathcal{X}$ -measurable function.

By [6, Th. 10.7.2.], for any transition probability W and probability measure p on  $(\mathcal{X}, \mathcal{X})$  there exists a unique probability measure  $p \circledast W$  on  $(\mathcal{X} \times \mathcal{Y}, \mathcal{X} \otimes \mathcal{Y})$  satisfying

$$p \circledast W(\mathcal{E}_x \times \mathcal{E}_y) = \int_{\mathcal{E}_x} W(\mathcal{E}_y | x) p(\mathrm{d}x)$$

for all  $\mathcal{E}_x \in \mathcal{X}$  and  $\mathcal{E}_y \in \mathcal{Y}$ . Now, we can define the order  $\alpha$ Rényi information for p on the transition probability W.

Definition 10: For any  $\alpha \in [0, \infty]$ , transition probability W from  $(\mathfrak{X}, \mathfrak{X})$  to  $(\mathfrak{Y}, \mathfrak{Y})$ , and  $p \in \mathcal{P}(\mathfrak{X})$ , the order  $\alpha$  *Rényi information for prior* p is defined as

$$I_{\alpha}(p;W) \triangleq \inf_{q \in \mathcal{P}(\mathcal{Y})} D_{\alpha}(p \circledast W \| p \otimes q).$$
 (A.5)

Definitions 4 and 10 are equivalent because of Lemma 14. Using the definition of  $I_{\alpha}(p; W)$  we can define the order  $\alpha$ Rényi capacity of a transition probability W.

Definition 11: For any  $\alpha \in [0, \infty]$  and transition probability W from  $(\mathfrak{X}, \mathfrak{X})$  to  $(\mathfrak{Y}, \mathfrak{Y})$ , the order  $\alpha$  Rényi capacity is

$$C_{\alpha,W} \triangleq \sup_{p \in \mathcal{P}(\mathcal{X})} I_{\alpha}(p; W).$$
 (A.6)

The analysis of the Rényi capacity for an arbitrary transition probability W is beyond the scope of this paper. However, if the  $\sigma$ -algebra  $\mathcal{X}$  is countably separated, then we can use Theorem 1 to show that  $C_{\alpha,W} = C_{\alpha,W}$  for a  $\mathcal{W} \subset \mathcal{P}(\mathcal{Y})$ .

Theorem 3: For any  $\alpha \in (0, \infty]$  and transition probability W from  $(\mathfrak{X}, \mathfrak{X})$  to  $(\mathfrak{Y}, \mathfrak{Y})$  for a countably separated  $\sigma$ -algebra  $\mathfrak{X}$ 

$$C_{\alpha,W} = \sup_{p \in \mathcal{P}(\mathcal{X})} \inf_{q \in \mathcal{P}(\mathcal{Y})} D_{\alpha}(p \circledast W \| p \otimes q) \quad (A.7)$$

$$= \inf_{q \in \mathcal{P}(\mathcal{Y})} \sup_{p \in \mathcal{P}(\mathcal{X})} D_{\alpha}(p \otimes W \| p \otimes q) \quad (A.8)$$

$$= \inf_{q \in \mathcal{P}(\mathcal{Y})} \sup_{w \in \mathcal{W}} D_{\alpha}(w \parallel q)$$
(A.9)

where  $\mathcal{W} \triangleq \{W(\cdot|x) : x \in \mathcal{X}\}$ . If  $C_{\alpha,W} < \infty$ , then there exists a unique  $q_{\alpha,W}$  in  $\mathcal{P}(\mathcal{Y})$ , called the order  $\alpha$  Rényi center, such

that

$$C_{\alpha,W} = \sup_{p \in \mathcal{P}(\mathcal{X})} D_{\alpha} \left( p \circledast W \| p \otimes q_{\alpha,W} \right)$$
(A.10)

$$= \sup_{w \in \mathcal{W}} D_{\alpha} \left( w \| q_{\alpha, W} \right). \tag{A.11}$$

Proof of Theorem 3: Since  $\mathcal{X}$  is countably separated, all singletons are in  $\mathcal{X}$  by [6, Th. 6.5.7] and  $\mathcal{P}(\mathcal{X}) \subset \mathcal{P}(\mathcal{X})$ . Consequently, using max-min inequality we get

$$\begin{aligned} \sup_{p \in \mathcal{P}(\mathcal{W})} \inf_{q \in \mathcal{P}(\mathcal{Y})} D_{\alpha}(p \circledast \mathcal{W} \| p \otimes q) \\ &\leq \sup_{p \in \mathcal{P}(\mathcal{X})} \inf_{q \in \mathcal{P}(\mathcal{Y})} D_{\alpha}(p \circledast W \| p \otimes q) \\ &\leq \inf_{q \in \mathcal{P}(\mathcal{Y})} \sup_{p \in \mathcal{P}(\mathcal{X})} D_{\alpha}(p \circledast W \| p \otimes q) \quad (A.12) \end{aligned}$$

On the other hand, for any  $\alpha \in (0, \infty]$  as a result of Tonelli-Fubini theorem [17, Th. 4.4.5] and the definition of the Rényi divergence given in (19) we have

$$D_{\alpha}(p \circledast W \| p \otimes q) \leq \sup_{x \in \mathcal{X}} D_{\alpha}(W(\cdot | x) \| q)$$
  
=  $\sup_{w \in \mathcal{W}} D_{\alpha}(w \| q)$ . (A.13)

Hence,

$$\inf_{q \in \mathcal{P}(\mathcal{Y})} \sup_{p \in \mathcal{P}(\mathcal{X})} D_{\alpha}(p \otimes W \| p \otimes q) \\ \leq \inf_{q \in \mathcal{P}(\mathcal{Y})} \sup_{w \in \mathcal{W}} D_{\alpha}(w \| q). \quad (A.14)$$

Theorem 1 and the inequalities given in (A.12), (A.13), and (A.14) imply  $C_{\alpha,W} = C_{\alpha,W}$  and Theorem 3 for  $q_{\alpha,W} = q_{\alpha,W}$ .

#### ACKNOWLEDGMENT

The author would like to thank F. Nakiboğlu and M. Nakiboğlu for their hospitality; this work simply would not have been possible without it. He would like to thank I. Csiszár for pointing out Agustin's work at Austin in 2010 ISIT, H. R. Palaiyanur for sending him Augustin's manuscript [5], Reviewer I for pointing out [35], [39], [44], [45], [53], [65], and [75], and G. Nakiboğlu, R. G. Gallager, H. C. Cheng, and the reviewers for their suggestions on the manuscript.

**Barış Nakiboğlu** received the B.S. degrees in electrical and electronics engineering and in physics from Middle East Technical University (METU), Ankara, Turkey, in 2002 and the M.S. degree in electrical engineering and computer science and the Ph.D. degree in electrical engineering from the Massachusetts Institute of Technology (MIT), Cambridge, Massachusetts, in 2005 and 2011, respectively. He was a postdoctoral scholar at the University of California Berkeley during the 2012-2013 academic year. He is with the Department of Electrical and Electronics Engineering at METU.
